Abstract

The following paper includes a derivation of practical Kedem-Katchalsky (K-K) equations for the volume flow \(J_v\) and the solute flow \(J_s\) for non-electrolytes. This derivation makes the equations clearer and consequently their interpretation also becomes easier. The equations have been derived on the basis of the analysis of the membrane transport generated by simultaneous action of two thermodynamic stimuli: the hydrostatic
pressure difference $\Delta p$ and the osmotic pressure difference $\Delta \Pi$. Furthermore, the derivation of the solute permeability coefficient $\omega$, which results from K-K equations, is also presented in this paper. The formulas for coefficients characterizing membrane permeability, $\omega_d$ and $\omega_k$, as well as their derivation and physical interpretation are also presented below. Finally, a formula for the membrane coefficient $L_D$, which represents a diffusional mobility, is derived.
1 Introduction

Membrane transport for binary non-electrolyte solutions, generated by the hydrostatic pressure difference $\Delta p$ and the osmotic pressure difference $\Delta \Pi$, can be described by practical Kedem-Katchalsky equations. The K-K equations have been derived from the principles of linear thermodynamics of irreversible processes. Such membrane transport is described by the equations for the volume flow $J_\nu$ and the solute flow $J_s$ [1-4]:

$$J_\nu = L_p \Delta P - L_p \sigma \Delta \Pi,$$

$$J_s = \omega \Delta \Pi + \bar{c}(1 - \sigma)J_\nu,$$

where $\bar{c}$ stands for mean concentration, $\bar{c} \approx \frac{1}{2}(c_1 + c_2)$ and $(L_p, \sigma, \omega)$ are coefficients of filtration, reflection and permeation, respectively.

The above equations have widely been used in research on substance permeability through artificial and biological membranes [6, 11]. This paper includes a complete analysis and interpretation of the K-K equations. Some preliminary results in this field are presented in Ref. [15].

In the following paper the transport K-K equations have been derived on the basis of phenomenological equations. Consequently, the K-K equations have become more comprehensible and we can interpret them thoroughly. It is important from biological point of view since the effects of substance transport through biological and artificial membranes can be understood easily, whereas the application of the K-K equations in their classical version is limited to membrane systems with two-component solutions, sufficiently diluted and well stirred [7, 9,16]. The presented way of deriving these equations leads to the derivation of membrane permeability parameters $\omega_d$, $\omega_k$ as well as $L_D$ parameter. The physical meaning of these parameters is presented further in the paper.

2 Scheme of the solute fluxes across a membrane

Fig. 1 depicts a cell, which consist of two compartments with a solution separated by the membrane in isothermal conditions. Substance transport is generated by the simultaneous action of two stimuli: the osmotic pressure difference and the mechanical pressure difference. The solute fluxes transport through the membrane is described in the text.
The above K-K equations, (1) and (2), are derived on the basis of linear thermodynamics of irreversible processes. Membrane transport is generated by two thermodynamic stimuli: $\Delta p$ and $\Delta \Pi$. In the method developed here, the analysis of the membrane transport is presented for the case of a homogeneous membrane, which separates two aqueous well-mixed solutions of a non-electrolyte with two-component solutions. There are the following conditions inside the compartments: $c_1 > c_2$ and $p_1 > p_2$. The osmotic pressure difference $\Delta \Pi$, on the basis of vант Hoff's formula, is assumed as $\Delta \Pi = RT \Delta c$ where $\Delta c = c_1 - c_2$ is the concentration difference [5, 14] while $R$ and $T$ are the gas constant and thermodynamic temperature, respectively. The hydrostatic pressure difference $\Delta p = p_1 - p_2$. According to the isothermal conditions, the temperature gradient equals 0.
3 Derivation of Kedem-Katchalsky equations for membrane transport from phenomenological equations

Dissipation function $\Phi$ for the membrane of thickness $\Delta x$ is given by the following formula (Katchalsky and Curran, 1965):

$$\Phi dx = \Phi = \sum_{i=1}^{n} J_i \Delta \mu_i = J_w \Delta \mu_w + J_s \Delta \mu_s,$$

(3)

where $J_i$ is the volume flow, and $\mu_i$ is the chemical potential of solution components. Equation (3) describes $n$ different flows in terms of $n$ forces. The subscripts $w$ and $s$ denote the solvent and the solute, respectively. Provided the chemical potentials at the membrane surfaces are identical to the corresponding chemical potentials in the solutions, $\Phi$ can be expressed as [2]

$$\Phi = (J_w \tilde{V}_w + J_s \tilde{V}_s) \Delta p + \left( \frac{J_s}{c_s} \right) \Delta \Pi,$$

(4)

where $\tilde{V}_w$ and $\tilde{V}_s$ are the partial molar volume of solvent and solute; $J_w$ and $J_s$ are flows of solvent and solute, respectively. We obtain the transformed dissipation function in the following form

$$\Phi = J_\nu \Delta p + J_D \Delta \Pi.$$

(5)

In the conditions of two thermodynamic stimuli $\Delta p$ and $\Delta \Pi$, the phenomenological K-K equations for the volume flow ($J_\nu$) and the diffusion flow ($J_D$) through the membrane and the forces defined by Eq. (5) can be written as

$$J_\nu = L_p \Delta p + L_{pd} \Delta \Pi,$$

(6)

$$J_D = L_{dp} \Delta p + L_D \Delta \Pi,$$

(7)

where $L_p$, $L_{dp}$, $L_{pd}$ and $L_D$ are coefficients of the membrane (filtration, ultrafiltration, osmotic and diffusional, respectively). If $\Delta p = \Delta P_i$, then $L_p = -L_{pd} = L_D$; $J_D$ is the diffusional flow.
3.1 Equation for the volume flow $J_\nu$

The overall volume flow $J_\nu$ is equal to the sum of the volume flux caused by $\Delta p$ and the volume flux caused by $\Delta P_i$. This overall volume flow $J_\nu$ can be given by Eq. (6).

Making use of the reflection coefficient $\sigma$, introduced originally by Staverman (1951), we can write

$$\sigma = -\frac{L_p D}{L_p}.$$  

(8)

As a result, equation (9), written below, has exactly the same form as Kedem-Katchalsky Eq. (1):

$$J_\nu = L_p \Delta P - L_p \sigma \Delta \Pi.$$  

(9)

The relation among transport parameters $L_p$ and $\sigma$ is expressed in the following definition:

$$L_p = \left( \frac{J_\nu}{\Delta p} \right)_{\Delta \Pi = 0}.$$  

(10)

The parameter $L_p$ is the hydraulic conductivity or the mechanical filtration coefficient of a given membrane. This coefficient has the character of mobility and represents the velocity of fluid per unit of pressure difference [7]. It expresses the overall filtration properties of all pores within a given membrane.

The parameter $\sigma$ is the reflection coefficient. If $\sigma = 1$, the membrane is semi-permeable, what means that it is permeable only for the solvent but not for the solute molecules, which are reflected. If $\sigma = 0$, the membrane is not selective, so every pore of the membrane is permeable for the solvent as well as for the solute. If $0 < \sigma < 1$, the membrane is selective, which means that it has pores with differentiated diameters [6, 8].

3.2 Equation for the solute flow ($J_s$)

The overall solute flow $J_s$ through the membrane, generated by $\Delta p$ and $\Delta \Pi$, can be written in the following form [2]

$$J_s = \bar{c}(J_\nu + J_D).$$  

(11)
Kedem-Katchalsky equations for membrane substance transport

For such a membrane, the Onsager reciprocal relation (ORR) is given by

\[ L_{PD} = L_{DP}. \]  \hfill (12)

Using Eqs. (6), (7) and (12), we can write Eq. (11) for the total solute flow as follows:

\[
J_s = \bar{c}(L_p \Delta p + L_{PD} \Delta \Pi + \bar{c}L_p \Delta p + L_D \Delta \Pi) \Delta p,
\]

\[
= \bar{c}L_D \Delta \Pi + \bar{c}L_{PD} \Delta \Pi + \bar{c}(L_p + L_{DP}) \Delta p,
\]

where \( L_p \Delta p \) is the hydraulic term; \( L_{PD} \Delta \Pi \) is the osmotic term; \( L_{DP} \Delta p \) is the ultrafiltration term and \( L_D \Delta \Pi \) is the diffusional term.

Next, according to Eq. (8), Eq. (13) can be expressed as:

\[
J_s = \omega_d \Delta \Pi + \bar{c}(1 - \sigma)L_p \Delta p.
\]

After taking Eq. (6) into account and after some transformations, Eq. (14) can be written as:

\[
J_s = \bar{c}L_D \Delta \Pi + \bar{c}L_{PD} \Delta \Pi + \bar{c}(1 - \sigma)(J_v - L_{PD} \Delta \Pi)
\]

\[
= \bar{c}L_D \Delta \Pi + \bar{c}\sigma L_{PD} \Delta \Pi + \bar{c}(1 - \sigma) J_v.
\]

Using Eq. (8), we can express Eq. (15) in the following form:

\[
J_s = \bar{c}\left(\frac{L_DL_p - L_{PD}^2}{L_p}\right) \Delta \Pi + \bar{c}(1 - \sigma) J_v.
\]

If in Eq. (16) we insert the coefficient \([2]\):

\[
\omega = \left(\frac{J_s}{\Delta \Pi J_v=0}\right) = \bar{c}\left(\frac{L_DL_p - L_{PD}^2}{L_p}\right),
\]

then Eq. (16) for the solute flow \( J_s \) has the same form as Kedem-Katchalsky Eq. (2):

\[
J_s = \omega \Delta \Pi + \bar{c}(1 - \sigma) J_v.
\]

The phenomenological K-K equations can also be written in the following form \([12, 13]\):

\[
J_v = L_p \Delta p - L_{PD} \Delta \Pi,
\]

\[
J_D = -L_{DP} \Delta p + L_D \Delta \Pi.
\]
3.3 Equation for the volume flow \((J_\nu)\)

Taking Eqs. (19) and (20) into account, we can rewrite the Stavermann relation, given by Eq. (8), in the following form [6, 12, 13]:

\[
\sigma = \frac{L_p D}{L_p \Delta p}.
\]  

(21)

According to Eq. (21), Eq. (19) for the volume flow \(J_\nu\) can be expressed in the same way as Kedem-Katchalsky Eq. (1):

\[
J_\nu = L_p \Delta p - L_p \sigma \Delta \Pi.
\]  

(22)

3.4 Equation for the solute flow \((J_s)\)

According to Eqs. (12), (19) and (20), equation (11) for the total solute flow \(J_s\) can be written as follows

\[
J_s = \bar{c}(L_p \Delta p - L_p D \Delta \Pi - L_{DP} \Delta p + L_D \Delta \Pi) - \bar{c}(L_p - L_{DP}) \Delta p + \bar{c} L_D \Delta \Pi - \bar{c} L_{PD} \Delta \Pi.
\]  

(23)

Using Eq. (21) and Eq. (19) we obtain:

\[
J_s = \bar{c}(1 - \sigma) L_p \Delta p + \bar{c} L_D \Delta \Pi - \bar{c} L_{PD} \Delta \Pi
\]  

(24)

\[
= \bar{c}(1 - \sigma)(J_\nu + L_{PD} \Delta \Pi) + \bar{c} L_D \Delta \Pi - \bar{c} L_{PD} \Delta \Pi
\]

\[
= \bar{c}(L_D - \sigma L_{PD}) \Delta \Pi + \bar{c}(1 - \sigma) J_\nu
\]

\[
= \bar{c} \left( \frac{L_D L_p - L_{PD}^2}{L_p} \right) \Delta \Pi + \bar{c}(1 - \sigma) J_\nu.
\]

If in Eq. (24) we insert Eq. (17) for the coefficient \(\omega\), then the equation Eq. (24) for the solute flow \(J_s\) has the same form as Eq. (2):

\[
J_s = \omega \Delta \Pi + \bar{c}(1 - \sigma) J_\nu,
\]  

(25)

where \(\omega\) is the coefficient of a solute permeability at \(J_\nu = 0\). It expresses the permeation of all pores of a given membrane with simultaneous action of both stimuli, \(\Delta \Pi\) and \(\Delta p\).
4 Derivation of membrane transport parameters: \( \omega_d, \omega_k \) and \( L_D \)

4.1 Membrane permeation coefficient \( \omega_d \)

Parameter \( \omega_d \) is a coefficient expressing permeation of all pores of a given membrane for the solute flow due to the presence of \( \Delta \Pi \) stimulus, when \( \Delta p = 0 \). For the sake of its derivation, we define the coefficient \( \omega_d \) in the following way

\[
\omega_d = \left( \frac{J_s}{\Delta \Pi} \right)_{\Delta p=0}.
\]  

(26)

Using Eqs. (9) and (18), we obtain the following relation:

\[
J_s = \omega \Delta \Pi + \bar{c}(1 - \sigma)(L_p \Delta p - L_p \sigma \Delta \Pi)
\]

\[
= [\omega - \bar{c}(1 - \sigma)L_p \sigma] \Delta \Pi + \bar{c}(1 - \sigma)L_p \Delta p.
\]

(27)

When \( \Delta p = 0 \), Eq. (27) takes on the form:

\[
(J_s)_{\Delta p=0} = (\omega - \bar{c}(1 - \sigma)L_p \sigma) \Delta \Pi.
\]  

(28)

The obtained equation, Eq. (28), allows one to calculate the \( \omega_d \) coefficient due to its definition given by Eq. (26). Therefore, \( \omega_d \) can be expressed as:

\[
\omega_d = \omega - (1 - \sigma)\bar{c}L_p \sigma.
\]  

(29)

Next, inserting Eq. (17) and Eq. (8) into Eq. (30), we get the final form of the \( \omega_d \) coefficient [11]:

\[
\omega_d = \bar{c}(L_D + \sigma L_{pD} - L_p \sigma + \sigma L_p \sigma)
\]

\[
= \bar{c}(L_D + L_{pD}).
\]

(30)

The coefficient \( \omega_d \), expressed by Eq. (30), can be interpreted more easily than the one expressed by Eq. (29). Moreover, the form of Eq. (30) makes membrane transport, described by practical Kedem-Katchalsky equations, more comprehensible.
4.2 Parameter $L_D$:

The above equations (30) and (29) can be written as follows:

$$\bar{c}(L_D + L_{pD}) = \omega - (1 - \sigma)\tilde{c}L_p\sigma.$$  \hfill (31)

The final formula describing transport parameter $L_D$ has the following form [11]:

$$L_D = \frac{\omega}{\bar{c}} + L_p\sigma^2.$$  \hfill (32)

The diffusional flow $J_D$, caused by the osmotic pressure difference, is characterized by the coefficient $L_D$. This coefficient represents diffusional mobility per unit of osmotic pressure [2]. Therefore, the coefficient $L_D$ can be defined as:

$$L_D = \left(\frac{J_D}{\Delta\Pi}\right)_{\Delta p=0}.$$  \hfill (33)

4.3 Transport parameter $\omega_k$

Parameter $\omega_k$ is a permeation coefficient of all pores of a given membrane for the solute flow due to the action of the hydrostatic pressure difference $\Delta p$, when $\Delta \Pi = 0$. The coefficient $\omega_k$ can be defined by means of the following formula

$$\omega_k = \left(\frac{J_s}{\Delta p}\right)_{\Delta \Pi=0}.$$  \hfill (34)

After taking Eqs. (18) and (9) into account, we obtain Eq. (33) in the following form

$$\omega_k = \bar{c}(1 - \sigma)L_p.$$  \hfill (35)

Inserting Eq. (8) into Eq. (34), we can write eventually the formula for the coefficient $\omega_k$ as:

$$\omega_k = \bar{c}(L_p + L_{DP}).$$  \hfill (36)
5 Conclusions

The analysis of the expressions for particular fluxes and other relations derived here, representing membrane permeation coefficients $\omega_d$, $\omega_k$, $\omega$ and parameter $L_D$, together with their physical interpretation, make practical K-K equations more straightforward and comprehensible. Hence, the physical interpretation of these equations seems to be easier now, while it has been considered as difficult especially in the case of the equation for the solute flow $J_s$.

The method presented here, which has resulted in the derivation of practical Kedem-Katchalsky equations for the volume flow $J_\nu$ and the solute flow $J_s$, allows one to carry out a more detailed and comprehensible analysis of results of the research on transport through biological and artificial membranes.

This paper is aimed to give more physical sense to the Kedem-Katchalsky (K-K) equations when considering the case of solvent and solute transport under the action of hydrostatic pressure and osmotic pressure gradient. It is a good way to clarify some chapters of the non-equilibrium thermodynamics.

This derivation, in particular makes the equation for solute flow ($J_s$) and the solute permeability coefficient ($\omega$) clearer and consequently their interpretation also becomes easier. Furthermore, this paper makes some new contribution to membrane expressed by the so called K-K equations. It includes a transformation of K-K equation on solute flow to its new form: $J_s = \omega_d \Delta \Pi + \bar{c}(1 - \sigma)L_p \Delta \rho$ as coefficient derivations which characterize the membrane ($\omega_d$ - the coefficient of diffusive solute permeation and $L_D$ - conductivity for
volume flow).

It should be emphasized that the K-K equation on solute flow transformed to a new form is more comprehensible. Together with the derivated parameters, it gives new opportunities for the research concerning solute permeation across biological and artificial membranes.
