Abstract
Aim: To assess the antimicrobial activity of various concentrations of Tulsi (Ocimum sanctum) extract, obtained from commercially available Tulsi powder, against Streptococcus mutans. Setting and design: Experimental design, in vitro study, Lab setting. Materials and methods: Ethanolic extract of Tulsi was prepared by the cold extraction method. The extract was then diluted with an inert solvent, dimethyl formamide, to obtain 7 different concentrations (2%, 3%, 4%, 5%, 6%, 7% and 8%). 0.2% chlorhexidine was used as a positive control and dimethyl formamide was used as a negative control. The extract, along with the controls, was then subjected to microbiological investigation to determine which concentration among the 7 different concentrations of the extract gave a wider inhibition zone against Streptococcus mutans. The zones of inhibition were measured in millimetres using a vernier caliper. Results: At the 6% concentration of Tulsi extract, a zone of inhibition of 27 millimetres (mm) was obtained at a volume of 50 µl. This was the widest zone of inhibition observed among all the 7 different concentrations of Tulsi that were investigated. Conclusion: Tulsi extract demonstrated an antimicrobial property against Streptococcus mutans and can be used as a mouthwash. This could be further confirmed by in-vivo studies.

Key words Antimicrobial activity, Ocimum Sanctum, Streptococcus mutans, tulsi extract

1. Introduction
Dental caries is a disease of complex etiology. Microorganisms play an important role in the etiology of dental caries. There is substantial evidence that suggests that Streptococcus mutans is one of the main culprit microorganisms responsible for dental caries[1]. Reducing their levels in the oral cavity would provide an additional rationale for the prevention of dental caries. The responsibility is on the dentist to come up with robust, innovative, effective, feasible and new strategies to manage the disease. One such strategy would be to verify the enormous wealth of medicinal plants. Finding healing powers in plants is an ancient idea. People on all continents have long applied poultices and imbibed infusions of hundreds of indigenous plants dating back to the pre-history eras. Currently, of the one-quarter to one half of all pharmaceuticals dispensed in the United States having plant origins, very few are intended for use as antimicrobials[2]. Tulsi, scientifically known as Ocimum sanctum, is a time-tested premier medicinal herb. It is a plant of Indian origin, worshipped by the Hindus and used in Ayurvedic medicine since ancient times. It is one of the holiest and most sacred herbs grown widely in India. It is a herb that is bestowed with enormous antimicrobial substances and is used to treat a variety of illnesses ranging from diabetes mellitus, arthritis, bronchitis, skin diseases, etc[3-5]. Recent studies have also demonstrated significant anticancer properties of Ocimum sanctum[6]. Hence, it is also termed as the queen of herbs or the mother medicine of nature.

Literature review reveals that the antimicrobial property of Tulsi has been tested against a variety of microorganisms like Candida albicans, Staphylococcus aureus, enteric pathogens, Klebsiella, Escherichia coli and Proteus[7]. It has also demonstrated anti-gonorrhoeal efficacy against multiresistant strains of Neisseria gonorrhoea and clinical isolates of beta lactamase-producing methicillin-resistant Staphylococcus aureus[8,9]. Chlorhexidine is used as a gold standard against which other antimicrobial agents are compared. It has been studied extensively and is currently the most potent chemotherapeutic agent against Streptococcus mutans and dental caries[10-13]. Consequently, chlorhexidine is also often used as a...

positive control for assessing the anticariogenic potential of other agents[14]. Therefore, an attempt is made to compare the antimicrobial activity of commercially available Tulsi powder with 0.2% chlorhexidine against *Streptococcus mutans*.

2. Methodology

An in-vitro study was designed to study and compare the antimicrobial activity of various concentrations of Tulsi (*Ocimum sanctum*) extract, obtained from commercially available Tulsi powder, against *Streptococcus mutans*.

**Preparation of Tulsi extract**

Commercially available Tulsi powder (Balaji’s Tulsi Herbal Powder) is taken for the study. Three hundred grams of finely powdered Tulsi is then macerated with 500 millilitre (ml) of 100% ethanol.

It is then subjected to filtration with Whatman filter paper to obtain a clear filtrate. The filtrate so obtained is reduced at a low temperature of less than 60°C to obtain a solid residue of Tulsi extract. From 300 grams of Tulsi powder dissolved in 1 litre (L) of ethanol, 18 grams of residue (extract) is obtained and thus the yield was 6% w/w (weight/weight)[15].

**Preparation of seven different concentrations of Tulsi extract**

One gram of extract is dissolved in 10 ml of dimethyl formamide to obtain a 10% concentration of extract. One millilitre of the extract is transferred to a sterilized test tube and labeled as 10%. The remaining 9 ml of the extract is then diluted further with dimethyl formamide to obtain seven different concentrations (2%, 3%, 4%, 5%, 6%, 7% and 8%).

0.2% chlorhexidine is used as a positive control as it is the most potent chemotherapeutic agent against *Streptococcus mutans*. Dimethyl formamide is used as a negative control as it is an inert solvent and *Streptococcus mutans* is resistant to it, and is used to dilute Tulsi extract and to neutralize the effect of alcohol.
Microbiological procedures

Pure strains of *Streptococcus mutans* (MTCC 890) are obtained from Microbial Type Culture Collection and Gene Bank (MTCC), Chandigarh.

Medium used

Brain heart infusion agar is used as a medium.

The cup and plate method is used to determine the zone of inhibition. In this method, three circular wells that could incorporate three different volumes (20 μl, 30 μl and 50 μl) of the test agent (Tulsi extract) are cut in the agar plates using a template.

Brain heart infusion agar is used as a medium.

Nine such plates were prepared and labeled, 07 for the 07 different concentrations of Tulsi extract (one plate each for one particular concentration) and one plate for positive control (chlorhexidine) and one plate for negative control (Dimethyl formamide), respectively.
Assessment of Antimicrobial Activity of Various Concentrations of Commercially Available Tulsi (Ocimum Sanctum) Powder Against Streptococcus Mutans

The different concentrations of extract, along with the controls, are transferred to the respective agar plates and these incubated aerobically at 37°C for 48 hours. The inhibition zones are measured using a vernier caliper[15].

Figure 12. Growth of Strept mutans on brain heart infusion agar

Statistical procedures

No statistical tests were performed as they were not required and the data obtained were appraised observationally.

3. Results

Table 1 shows zones of inhibition of different concentrations and volumes of tulsi extract.

At 2% concentration, maximum zone of inhibition of 13 mm was achieved at a volume of 50 µl. At lower volumes of 20 µl and 30 µl of 2% concentration, there were no zones of inhibition.

At 3% concentration, a maximum zone of inhibition of 15 mm was achieved at a volume of 50 µl. At lower volumes of 20 µl and 30 µl of 3% concentration, there were no zones of inhibition.

A maximum zone of inhibition of 16 mm was achieved at 4% concentration with 50 µl volume. At lower volumes of 20 µl and 30 µl at 4% concentration, the zones of inhibition were 10 mm and 14 mm respectively.

At 5% concentration, a maximum zone of inhibition of 20 mm was achieved at a volume of 50 µl. At lower volumes of 20 µl and 30 µl at 5% concentration, the zones of inhibition were 16 mm and 18 mm respectively.

However, at 6% concentration, a maximum zone of inhibition of 27 mm was achieved at a volume of 50 µl. At lower volumes of 20 µl and 30 µl at 6% concentration, the zones of inhibition were 16 mm and 25 mm respectively.

At 7% concentration, a maximum zone of inhibition of 16 mm was achieved at a volume of 50 µl. At lower volumes of 20 µl and 30 µl at 7% concentration, the zones of inhibition were 10 mm and 14 mm respectively.

At 8% concentration, a maximum zone of inhibition of 18 mm was achieved with 50 µl volume. At lower volumes of 20 µl and 30 µl at 8% concentration, the zones of inhibition were 11 mm and 16 mm respectively.

Table 2 shows zones of inhibition of different volumes at a concentration of 0.2% chlorhexidine (positive control).

4. Discussion

_Ocimum sanctum_ Linn., the plants of genus Ocimum belonging to family Labiatae are very important for their therapeutic potentials[16,17]. It is a multi-branched, small, erect, soft, stout and aromatic herb about 75 cm high. This is commonly known as Vishnu-Priya, Tulsi in Sanskrit, Kala-Tulsi in Hindi and India’s Holy Basil in English.

It is found and cultivated throughout India and worshiped in temples and houses of Hindus.

Commonly, two types of _Ocimum sanctum_ Linn (_Ocimum sanctum_ L) are cultivated, namely tulsi plants with green leaves known as Sri Tulsi & tulsi plants with purple leaves known as Krishna Tulsi. The leaves, seeds and root of this plant have been used in indigenous Ayurvedic medicine for therapeutic purposes as an expectorant, analgesic, anticancer, anti-asthmatic, anti-atherosclerotic, anti-diabetic, anti-fertility, hepatoprotective, hypotensive, hypolipidemic, and anti-stress agents. Tulsi has also been used in treatment of fever, bronchitis, arthritis, convulsions etc[3, 18].

The chemical composition of Tulsi is highly complex, containing many nutrients and other biologically active compounds. The nutritional and pharmacological properties of the whole herb in its natural form result from synergistic interactions of many different active phytochemicals. Although Tulsi is known as a general vitalizer and increases physical endurance, it contains no caffeine or other stimulants[19]. The therapeutic potential of Tulsi has been found to be largely due to eugenol, a major constituent of the essential oil, which is a phenolic compound (1-hydroxy-2-methoxy-4-allylbenzene). The other important constituents include ursolic acid and carvacrol which also has antimicrobial activity[3].

In the present study, commercially available tulsi powder (Balaji’s Tulsi Herbal Powder) was used to compare the antimicrobial activity with 0.2% chlorhexidine (positive control) against _Streptococcus mutans_. Ethanol, a type of alcohol, was used as a solvent because the essential oils in Tulsi were more soluble in alcohol as compared to distilled water. Dimethyl formamide was used as a negative control in this study. It was an inert solvent and used to dilute the tulsi extract and to neutralize the effect of alcohol, attributing the result solely to tulsi.

In the present study, 6% concentration of Tulsi extract, obtained from commercially available Tulsi powder was found most effective and had maximum antimicrobial potential against _Streptococcus mutans_ (Table 1). However, Agarwal et al[15] reported 4% concentration of Tulsi extract, when Tulsi leaves were obtained from courtyard, had maximum antimicrobial potential against _Streptococcus mutans_. The difference demonstrated in the antimicrobial activity potential against _Streptococcus mutans_ might be due to using of commercial Tulsi powder in this study for preparing Tulsi extract, which might not be equally pure as Tulsi extract prepared from Tulsi leaves directly obtained from courtyard.

In the present study, chlorhexidine (positive control) was found to be more effective when compared to Tulsi extract, obtained from commercially available Tulsi powder (Table 2). However, the well-known side-effect of Chlorhexidine, i.e. staining of teeth and restoration, alteration of taste sensation and development of resistant microorganisms, may limit the long-term use of chlorhexidine[20]. In comparison with herbal medicines, Tulsi is abundantly available, easily accessible, economically feasible and culturally acceptable and may possess minimal side-effects, hence it can be recommended for long-term use[21].

In the present study, _Streptococcus mutans_ was resistant to dimethyl formamide (Table 3). Agarwal et al[15] also reported _Streptococcus mutans_ resistance against dimethyl formamide. This was due to fact that it was an inert solvent and used to dilute the tulsi extract and to neutralize the effect of alcohol, attributing the result solely to tulsi.

5. Conclusion

The present study demonstrated the maximum antimicrobial activity against _Streptococcus mutans_, using tulsi extract, obtained from commercially available Tulsi powder, at 6% concentration level and can be used as a mouthwash. However, further studies are required to confirm the composition and side effects of tulsi extract, obtained from commercially available Tulsi powder on human beings.
