Abstract       The increase in longevity and incidence of chronic diseases reveals an increased importance in terms of public health. The oncologic illness is a debilitating and progressive pathology with need for prevention and symptomatic relief. In order to find the answer to the question: “What is the effect of massage therapy in cancer patients?” we have reviewed the empirical literature indexed in databases online, finding only 21 articles published between 1990 and 2015. It was possible to verify some of the effects of massage therapy, particularly in relieving pain, decreased anxiety, depression and nausea and increased well-being. However, it was not found the effect of this intervention on the relief of suffering and the quality of life of patients. With the heterogeneity of methodologies, studies suggest the development of more homogeneous research, materials and methods to assess the effects of massage therapy in cancer patients.

Keywords       Patients, Oncology, Massage

1. Introduction

Massage therapy results in touch and its goals are varied including: the ability to help the body relax, feeling pleasure to overcome physical problems, releasing emotional blocks, and easing of pain among others.

This type of massage is a method of treatment used in curing a disorder. The massage can be applied for therapeutic purposes to assist in restoring the balance of the various human structures. It is also assumed that its application triggers mechanical effects, painkillers, psychological, structural and thermal effects, which are in line with the main purpose of our report.

According to Meleis[18], the purpose of the nurse is to interact with humans in situations of health or disease, to improve the cultural and social context where they are inserted because they are suffering some kind of transition or anticipating the same. As for the nurse-patient interactions, these can be organized around a main purpose and the nurse uses some therapeutic actions to improve, bring or facilitate the patient’s health.

In a second phase, with this report, we can analyse the effect of massage therapy on cancer patients. Being so, we have seen the number of patients with psychological changes increase, including depression, which decreases the quality of life of these patients and the depressive symptoms. This can actually generate a bigger limitation than the cancer itself and can cause suicide in about 50% of the patients. In turn, the anxiety has a prevalence rate of 18-35.1% (Castro, Scorza & Chem[7]).

Among cancer patients, more than 70% of them suffer from pain caused by disease and/or by handling. Patients in advanced stages of cancer describe the pain as moderate or severe in approximately 40 to 50%, and, according to Bair et al.[4] in 25-30% of the patients. In 2004, the Hospice and Palliative Nurse Association has developed a document concerning the pain where it is quoted that this vital sign is one of the most feared by patients in end-of-life. Therefore, it increases the physiological stress and decreases morbidity by adding the risk of thromboembolism in these patients (Runnig, Shreffler-Grant & Andrews[22]). The skills of nurses can provide care to a patient in chronic condition aimed at caring for the person with the disease, lessening the suffering, maximizing their well-being, comfort and quality of life (Ordem dos Enfermeiros[20]).

Nurses are crucial elements of a multidisciplinary team because they are actively involved in monitoring and pain relief, which requires the screening of the psychological, cognitive and emotional components of pain, including anxiety, depression and grief. Nurses also have previous experience in dealing with the pain, lack a personal, cultural and spiritual influence and can advise the prescription of non-pharmacological interventions in complementarity but not in replacement of pharmacological therapy, knowing their indications, contraindications and side effects (Ordem dos Enfermeiros[19]; Direção Geral de Saúde[10]).
The massage can be curative and preventive, as it can rehabilitate and relief of muscle tension. Patients who benefit from these interventions exhibit lower levels of anxiety and pain, having more control over treatment decisions (Almeida e Duarte[3]).

Based on the assumption that massage is beneficial to improve the patient's health condition, this literature review has found answers for the question "what is the effect of massage therapy on cancer patients?". Being so, the conclusion is that the purpose of the analysis conducted in this topic was achieved.

2. Methodology

This research was based on a systematic review of the literature with narrative summary. It was held exclusively in online databases, including EBSCOhost (Medline, Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, Psychology and Behavioural Sciences Collection, EJS E-Journals, and British Nursing Index), SciELO and RCAAP (open access Scientific Repository of Portugal). As inclusion criteria, we consider articles reported in the period between 1990 and 2015, in full-text and about massage therapy in adult patients with medical diagnosis of cancer. The articles that didn’t report the investigation around the theme under study and that did not present the predefined inclusion criteria were deleted.

The research selected 120 articles, including 50 articles on EBSCOhost, 10 on Scielo and 60 in RCAAP, through the keywords for palliative care, oncology, cancer and massage therapy. Some articles had common databases and after full thorough reading, 21 studies were selected for systematic review. The remaining articles have been removed for not meeting the inclusion criteria (table 1).

Table 1. Reduction scheme

| 120 articles in the databases online | 80 deleted based on review of the title and summary and criteria for inclusion |
| 40 articles in the databases online | 19 excluded by the inadequate description of the data collection instruments |
| Total = 21 articles in the databases online | |

---

The massage can be curative and preventive, as it can rehabilitate and relief of muscle tension. Patients who benefit from these interventions exhibit lower levels of anxiety and pain, having more control over treatment decisions (Almeida e Duarte[3]).

Based on the assumption that massage is beneficial to improve the patient's health condition, this literature review has found answers for the question "what is the effect of massage therapy on cancer patients?". Being so, the conclusion is that the purpose of the analysis conducted in this topic was achieved.

| 40 articles in the databases online | 19 excluded by the inadequate description of the data collection instruments |
| Total = 21 articles in the databases online | |
After an analysis and synthesis of selected articles, a summary table was created contemplating information extracted from each article and a descriptive analysis of the results.

### 3. Results

The synopsis of the articles and selected studies was described under paragraph 1, in accordance with the year of publication, study goals, type of study, methods, and results. In relation to the year of publication, it was identified the prevalence of studies published in 2004, 2007 and 2008, with 3 articles each. 2 articles were published in the years 2000, 2003, and 2009, and the rest only obtained a publication for each date mentioned. It was observed that the intervention of massage therapy in oncology nursing professionals offers a limited number of researches, although with some concern over the past fifteen years. Methodologically, it was found that the majority of studies are the quantitative paradigm.

The most commonly data collection instruments used was the Visual analogue scale (EVA) for the assessment of symptoms, including pain, anxiety, and nausea. It was also observed the use of scale Brief Pain Index (BPI) for the assessment of pain and State-Trait Anxiety Inventory (STAI) for evaluation of anxiety. Only one article used mixed qualitative and quantitative methodology, combining the EVA and the interview as methods. Through the analysis of the results of the studies selected, we categorized them according to the focus of nursing – (Classificação Internacional para a Prática de Enfermagem - CIPE), including pain, anxiety, depression, discomfort and suffering.

Taking into account the main results, it can be enhanced that massage therapy reduces: immediate levels of pain in male cancer patients (Weinrich & Weinrich[26]), pain levels of approximately 50% plus an improvement of 10% in sick bay rather than in the relocation and more durability of such reduction in pain (Cassileth & Vickers[6]), the intensity of the pain between 60% (Ferrell-Torry & Glick[13]) and 42% (Wilkie et al.[27]), as well as its average decrease of 5.50 to 3.83 (Toth et al.[25]) and 5.18 to 2.33 values (Adams, White & Beckett[1]). Also, through the qualitative results enhance improvements of total pain (Adams et al. [1]). This procedure significantly reduces the levels of pain (Post-White, Kinney, Savik, Gau & Lerner[21]; Currin & Meister[8]; Young[29]), either immediately (Grealish, Lomasney, & Whiteman[14]; Kutner, Smith, Corbin, Kemphill, Benton & Mellis[17]; Sui-Whi, et al.[24], short-term (20/30 minutes) and long term (16/18 hours) (Sui-Whi, et al.[24]), although the most significant impact occurred in the first few minutes after the intervention (Jane et al.[16]). It also showed a decrease in analgesics used and consumption of rescue analgesics (Post-White, Kinney, Savik, Gau & Lerner[21]; Deng & Cassileth[9]), although the consumption of morphine was held for 10 days. Nevertheless, there was a reduction in levels of pain after the 5th day (Ferreira & Lauretti[12]). However, there is a study which does not have significant differences that confirms the decline in the use of painkillers (Ferreira & Lauretti[12]; Kutner et al.[17]). Likewise, it was not shown significant changes in the long term benefits of massage in terms of improvement and pain control (Ferreira & Lauretti[12]; Kutner et al.[17]). These results corroborate a study, that although there was a decrease of pain, the difference was not statistically significant (Deng & Cassileth[9]).

As for anxiety, there was a decrease of anxiety with 24% (Ferrell-Torry & Glick[13]) and 50% (Cassileth & Vickers[6]), however only a study anxiety increased from 3.83 to 4.75 (Toth et al.[25]). Other studies showed a significant reduction in anxiety and depression after massage therapy (Post-White, Kinney, Savik, Gau & Lerner[21]; Hernandez-Reif, Ironson, Field, Hurley, Katz & Diego[15]; Cassileth & Vickers[6]; Deng & Cassileth[9]; Young[29]; Jane et al. [16])

Massage therapy has immediate effect on reducing depression and anxiety and also long-term depression (Soden, Vincent, Craske[23]; Hernandez-Reif et al.[15]). However, there are studies in which there were no differences in short term between anxiety and depression (Ahles et al.[2]) or that there were no significant differences of depression and anxiety in the long term (Billhult, Bergbom & Stenes-Victorin[5]). Another study confirms these results, noting that there were no significant differences in improvement of anxiety and depression. However, by structured interviews, the self-report of anxiety has improved for patients who received massage therapy. This relationship did not exist for the self-report of depression (Wilkinson et al.[28]).

As far as the other variables studied, the massage contributes for the immediate reduction of nausea (Ahles et al.[2]; Grealish, Lomasney, & Whiteman[14]; Cassileth & Vickers[6]; Billhult et al.[5]), although it was mentioned the non-existence of significant differences of this long-term variable (Ahles et al.[2]; Post-White et al.[21]). It was referred the reduction of blood pressure, heart rate and breathing, indicating the relaxing action of massage therapy (Ferrell-Torry & Glick[13]; Post-White et al.[21]; Deng & Cassileth[9]). The complement of this intervention increases the relaxation (Ferrell-Torry & Glick[13]; Grealish, Lomasney, & Whiteman[14]; Adams et al.[1]), because they have immediate effect in depressed mood and anger (Hernandez-Reif, Ironson, Field, Hurley, Katz & Diego[15]; Kutner et al.[17]). This intervention significantly decreases the incidence of muscular fatigue (Cassileth & Vickers[6]; Deng & Cassileth[9]; Currin & Meister[8]), reduces stress (Cassileth & Vickers[6]) and significantly improves the level of emotional well-being, relaxation and sleep patterns). It adds a significant decrease in dimensions of suffering in pain, physical and emotional discomfort, as well as on fatigue after massage (Currin & Meister[8]). The quality of life...
significantly improves (Ferreira e Lauretti[12]), but in the long term there was no statistically significant differences that could corroborate the improvement of quality of life, stress and suffering (Kutner et al.[17]; Soden et al.[23]).

### 4. Discussion

The results described above emphasize the current need to increase the empirical evidence as well as raise awareness of the benefits associated with this type of interventions that is carried out by nursing staff-therapeutic massage, focusing particularly on the level of patients with oncological pathology.

However, most studies in this systematic review enhance the effect of massage therapy on decreasing levels of pain and the intensity of some outbreaks that cause discomfort such as: providing relaxation, pleasure, avoiding physical problems, releasing emotional blocks, easing pain. In this particular case, it is up to the nurse to try to reduce the pain, anxiety, depression and discomfort.

Regarding pain, it was found on the basis of the described studies above, that the results converge because massage therapy decreases pain levels in some very significantly (Weinrich & Weinrich[26]; Ferrell-Torry & Glick[13]; Grealish, Lomasney, & Whiteman[14]; Wilkie et al.[27]; Toth et al. [25]; Post-White et al.[21]; Cassileth & Vickers[6]; Currin & Meister[8]; Young[29]; Jane et al. [16]; Adams, White & Beckett[1]; Sui-Whi, et al.[24]) and in others not so much (Deng & Cassileth[9]; Ferreira & Lauretti[12]; Kutner et al.[17]). We also note that there is the possibility of certain studies support that massage therapy causes patients to reduce the use of painkillers and recourse to SOS (Post-White, Kinney, Savik, Gau & Lerner[21]; Deng & Cassileth[9]). However, it was concluded that the differences are not that significant (Ferreira & Lauretti[12]; Kutner et al.[17]).

In terms of anxiety and depression, there were also contradictory results because some have revealed positive effects that patients feel in a short term (Post-White, Kinney, Savik, Gau & Lerner[21]; Hernandez-Reif, Ironson, Field, Hurley, Katz & Diego[15]; Cassileth & Vickers[6]; Deng & Cassileth[9]; Young[29]; Jane et al. [16]), other long-term (Soden, Vincent, Craske[23]; Hernandez-Reif et al.[15]) and others did not reveal any effects (Ahles et al.[2]).

There are also discrepancies about the other areas of nursing, with respect to the effectiveness of massage therapy, the level of nausea, as some studies consider that massage therapy has benefits (Ahles et al.[2]; Grealish, Lomasney, & Whiteman[14]; Cassileth & Vickers[6]) and others don't mention them (Ahles et al.[2]; Post-White et al. [21]).

However, it was found that this intervention has obtained positive results, associated with decreased vital signs due to the relaxation promoted (Ferrell-Torry & Glick[13]; Post-White et al.[21]; Deng & Cassileth[9]), in the depressed mood and anger (Hernandez-Reif, Ironson, Field, Hurley, Katz & Diego[15]; Kutner et al.[17]), on muscle fatigue (Cassileth & Vickers[6]; Deng & Cassileth[9]; Currin & Meister[8]), in stress (Cassileth & Vickers[6]) and the level of emotional well-being and sleep patterns (Soden et al.[23]; Adams et al.[1]). There were no statistical differences that could corroborate the improvement in quality of life, stress and suffering (Soden et al.[23]; Kutner et al.[17]), justifying...
the interest of this study.

5. Conclusions

Although the analysis of the results was contradictory in many cases and showed positive and negative or neutral data, the purpose of our study allowed us to conclude that massage therapy has beneficial effects. Being so, in a short term, the level of emotional well-being and relaxation increases, as physical and emotional discomfort, depressed mood, sleep patterns and stress decreases. The levels of quality of life and suffering are contradictory, reporting to future investigations continuity perspective.

Through this study, we found the need to step up the research in the field of nursing, broadening the field of nurses, leading to effective therapeutic interventions carried out by these professionals so that we can control and lessen the anxiety and depression.

The nurse has an important role in the patients’ recovery, highlighting their feelings and contributing to improve their self-esteem. In this sphere, the massage therapy intervention is essential, as the constant contact of the nurse with the patient encourages the implementation of these actions in order to relieve pain, promote common assistance and improve one’s quality of life.

It was noted also that the use of massage therapy is a reality in the universe of human health, nurses increasingly resorting to this type of interventions that had been used for a long time for the patient’s comfort. Our role as investigators and researchers is to establish scientifically the effects and benefits of this intervention, in order to add them to the non-pharmacological therapies that are already incorporated in the current health care system.

It is well known that even with the lack of research in this area, the nurses in their day-to-day work already use some therapies for pain control, such as relaxation techniques, cutaneous stimulation (massage, heat/cold, Transcutaneous electrical stimulation), etc..

It was found that the relaxation promotes the reduction of these factors, especially the muscle tension, improving the pain, because muscle contraction contributes to exacerbation of pain, focusing on the nerve endings, especially in chronic pain.

With the preparation of this study, we realised that massage therapy decreases total pain levels, both in a short or long term, and that, according to some authors, decreased the use of analgesics and the consumption of painkillers.

It seems that with the implementation of the relaxation massage, it can actually help rebalancing the body. However, most complementary therapies lead people to submit the relaxation response. Such techniques are related to existing interaction between pain, muscle tension and anxiety, because a patient with pain often presents feelings of apprehension and fear, leading to muscle tension which in turn worsens the pain.

It is important to note that the additional practices that can be used as non-pharmacological treatment of pain are two groups: techniques or methods carried out by nurses in the nursing consultation and that require expertise or professional qualification.

The care factors depend on the humanistic expectation, associated with the scientific knowledge and concept of mutuality that should exist between the nurse and the patient. That is why the nursing staff has the duty to be aware of the patient’s complaints. The body pain that is felt by the patient should always be monitored, so that his story is as improved and real as possible, regarding the evidence of pain and description of its intensity in order to have a combat intervention as efficient as possible.

One of the nurse’s contributions is the emphasis on care practice as interpersonal, based on factors that result in the satisfaction of human needs, promoting health, as well as an individual and family growth. It is essential to understand the environment as favouring the personal development and integrated in the biophysical and human behavioural knowledge.

Finally, and still on the basis of the results obtained, we also suggest the development of more research in order to give greater consistency to empirical effects of massage intervention, cancer patients and so contributing to the practice of nursing excellence based on evidence.
