Abstract
In this paper, a numerical approximation of the stress equation for the indentation of granular materials by a smooth rigid wedge is presented. Plane strain conditions are assumed, and the materials obey the Mohr-Coulomb yield condition. This method determines the deformation of granular material under a smooth rigid wedge punch and construction of stress field in the deforming region which are presented by using MATLAB programme. The granular material is assumed to be in dense, solid like state. The solution only refers to the initial motion after the punch. This was then applied on one type of boundary value problem. By using MATLAB, the value of each point \((x, y)\) and the stress variables \((p, \psi)\) which construct the deformation field are calculated. This method provides simple and reliable algorithms for the solution of the deformation problems involving the stress variables. The results will consequently help in the improvement of the existing labs and experimental facilities in the industries and will eventually increase its efficiency.

Keywords Deformation, Granular Material, Wedge Indentation

1. Introduction
The formulation of equations which govern the deformation and the flow of granular are outstanding problems in continuum mechanics. A review of a foundation theory in plasticity was made by [8]. This foundation is made based on the assumption of coaxiality of the principal stress and rate tensor. He proposed the boundary value problem for the numerical solution. By abandoning the assumption of coaxiality, an alternative family of models has been derived based on a kinematic hypothesis involving the concepts of shearing motion parallel to a surface, rotation of that surface, and dilation or contraction normal to the surface. One such model is the double-shearing theory, originally proposed by [7] for incompressible flows. The theory has been applied to the problem for the indentation of semi-infinite mass of soils by a smooth rigid flat punch. In this theory, the characteristic curves for the stresses and velocities coincide, and every deformation is assumed to consist of simultaneous shears along the two families of stress characteristics.

By applying the double slip and double spin model that was given by [14], the numerical approximation to the solution for double-slip and double-spin model for the deformation and flow of granular materials has been solved by [5]. The numerical approximation obtained then applied to some planar problems. The problem is considered is the indentation of granular material by a smooth rigid flat punch. Therefore, by applying Hill's boundary value problem and the slip line, theory and solution by [5], [7], [4] and [14], the aim of this study is to develop a numerical method to find the approximations for the indentation by a smooth rigid wedge punch for the granular materials.
The problem considered here is the indentation of a granular material by a smooth rigid wedge punch under the condition of plane strain. The behaviour of a granular material under an indenting rigid body is a fundamental problem with wide applications especially in engineering activities. This method provides simple and reliable algorithms for the solution of the granular deformation problem.

Shield[1] proposed a solution for the normal indentation of a granular material by a smooth rigid wedge in which the analysis is based on the assumption that the granular material obeys the Mohr-Coulomb yield criterion and its associated flow rule. The extension of indentation of a granular material by a smooth rigid wedge was presented in [2]{TA \ l "Tordesillas & Shi (1999)" \ c 1}. The authors presented a solution to the normal plane strain indentation of a double shearing dilatant granular material by a smooth rigid wedge. In this paper, we construct a numerical method of constructing stress deformation fields by using MATLAB program. In section 2, we summarize the basic governing equations for the plane deformations, while in the next section, we discuss the numerical method for the basic construction of stress characteristics field by using MATLAB program.

2. The Governing Equation for the Plane Deformation

In this section, the governing equations for the plane deformation of granular materials are presented. The equilibrium equations are given by

\[ \frac{\partial \sigma_{11}}{\partial x} + \frac{\partial \sigma_{12}}{\partial y} = 0 \]  
\[ \frac{\partial \sigma_{12}}{\partial x} + \frac{\partial \sigma_{22}}{\partial y} = 0 \]

with Mohr Coulomb yield criterion

\[ \tau = c - \sigma_n \tan \phi \]

where \( c \) is the cohesion, \( \sigma_n \) is the stress component and \( \phi \) is the internal friction of the material. Relative to the \( \alpha \) - an \( \beta \) -characteristic lines, the stress characteristic directions are given by

\[ dy \over dx = \tan \left( \psi - \frac{\pi}{4} - \frac{\phi}{2} \right) \]  
\[ dy \over dx = \tan \left( \psi + \frac{\pi}{4} + \frac{\phi}{2} \right) \]

which leads to the following governing stress equations for \( p \) and \( \psi \) given by

\[ \cos \phi \frac{\partial p}{\partial \sigma_\alpha} + 2q \frac{\partial \psi}{\partial \sigma_\alpha} = 0 \]  along the \( \alpha \)-characteristic

and

\[ \cos \phi \frac{\partial p}{\partial \sigma_\beta} - 2q \frac{\partial \psi}{\partial \sigma_\beta} = 0 \]  along the \( \beta \)-characteristic

where \( \psi \) represents the angle between the principal stress and the \( x \)-axis

\[ p = -\frac{1}{2} (\sigma_{11} + \sigma_{22}) \]  
\[ q = \frac{1}{2} (\sigma_{11} - \sigma_{22}) \]

Also, \( \frac{\partial}{\partial \sigma_\alpha}, \frac{\partial}{\partial \sigma_\beta} \) are directional derivatives along the \( \alpha \)- and \( \beta \)-characteristic lines.
3. Numerical Construction of the Stress Field

The stress field in the deformation region ABC under the contact surface is constructed by the network of intersection between $\alpha$-characteristic line AC and $\beta$-characteristic line BC as shown in Figure 2. Suppose that the smooth rigid wedge with semi-angle $\theta_1 = 45^\circ$ is indented into the granular material surface OE. The $\alpha$-characteristic line AC and $\beta$-characteristic line BC meets the contact surface at $\frac{\pi+2\phi}{4}$. The surface at $x > s$ is a stress-free surface which implies that the surface granular material is not subject to any force. The characteristics of granular material used in this study have the angle of internal friction, $\phi = \frac{\pi}{6}$ and the cohesion, $c = 2$. The depth of the penetration OA is denoted by $d$, while the distance between the free surface OE and B is denoted by $r$. The pressure distributions on the contact surface AB are assumed to be known. The surface AB is divided into $(n - 1)$ equal parts and each point are labelled as $ABC(i,1)$ where $i = 1, 2, 3, ..., n$. The coordinates $(x, y)$ and the stress variables $(p, \psi)$ are given along the contact surface AB. In this surface, following from [3], we shall assume that the stresses are constant, therefore the solution for $p$ and $\psi$ will yield a constant value. Then, from the known coordinates and the stress variables on AB, the stress field in the whole region ABC can be constructed numerically.

4. The Numerical Approximation of the Stress Field

The point ABC (1,1) and ABC (2,1) are the neighboring points on the contact surface AB, and the intersection of a $\beta$-characteristic line that passes through ABC(1,1) and the $\alpha$-characteristic line passing through ABC(2,1) is labelled as ABC(1,2) as shown in Figure 3.
The coordinates and the stress variables, \( p \) and \( \psi \), of point ABC(1,2) could be defined by employing the following numerical procedure.

Let the zeroth approximation for \( \psi_{\text{ABC}(1,2)} \) be taken as
\[
\psi_{\text{ABC}(1,2)}^0 = \frac{1}{2} \left( \psi_{\text{ABC}(2,1)} + \psi_{\text{ABC}(1,1)} \right)
\] (10)
and approximation to \( p_{\text{ABC}(1,2)} \) taken as
\[
p_{\text{ABC}(1,2)}^0 = \frac{1}{2} \left( p_{\text{ABC}(2,1)} + p_{\text{ABC}(1,1)} \right)
\] (11)

Let
\[
\psi^1_\alpha = \frac{1}{2} \left( \psi_{\text{ABC}(2,1)} + \psi_{\text{ABC}(1,2)}^0 \right) \text{ along the } \alpha \text{- characteristic line } ABC(2,1)ABC(1,2)
\] (12)
and
\[
\psi^1_\beta = \frac{1}{2} \left( \psi_{\text{ABC}(1,1)} + \psi_{\text{ABC}(1,2)}^0 \right) \text{ along the } \beta \text{- characteristic line } ABC(1,1)ABC(1,2).
\] (13)

Then, the coordinates at point ABC(1,2) are given by
\[
x_{ABC(1,2)}^1 = \frac{x_{ABC(1,1)}\tan(\psi_{\beta} + (\frac{\pi + 2\phi}{4})) - x_{ABC(2,1)}\tan(\psi_{\beta} - (\frac{\pi + 2\phi}{4})) + y_{ABC(2,1)} - y_{ABC(1,1)}}{\tan(\psi_{\beta} + (\frac{\pi + 2\phi}{4})) - \tan(\psi_{\beta} - (\frac{\pi + 2\phi}{4}))}
\]

\[
y_{ABC(1,2)}^1 = \frac{(x_{ABC(1,1)} - x_{ABC(2,1)})\tan(\psi_{\beta} + (\frac{\pi + 2\phi}{4})) + y_{ABC(2,1)} - y_{ABC(1,1)}\tan(\psi_{\beta} + (\frac{\pi + 2\phi}{4})) - y_{ABC(1,1)}\tan(\psi_{\beta} - (\frac{\pi + 2\phi}{4}))}{\tan(\psi_{\beta} + (\frac{\pi + 2\phi}{4})) - \tan(\psi_{\beta} - (\frac{\pi + 2\phi}{4}))}
\]

and the stress variables \((\psi_{ABC(1,2)}, p_{ABC(1,2)})\) are given by

\[
\psi_{ABC(1,2)}^1 = \frac{(p_{ABC(1,1)} - p_{ABC(1,1)})\cos\phi + 2q_{\alpha}\psi_{ABC(2,1)} + 2q_{\beta}\psi_{ABC(1,1)}}{2q_{\alpha}^2 + 2q_{\beta}^2}
\]

\[
p_{ABC(1,2)}^1 = \frac{p_{ABC(1,1)}\cos\phi + 2q_{\alpha}^2(\psi_{ABC(2,1)} - \psi_{ABC(1,2)})}{\cos\phi}
\]

where

\[
q_{\alpha}^1 = \frac{1}{2}(p_{ABC(2,1)} + p_{ABC(1,2)})\sin\phi + c\cos\phi \text{ along the } \alpha \text{- characteristic line } ABC(2,1)ABC(1,2)
\]

and

\[
q_{\beta}^1 = \frac{1}{2}(p_{ABC(1,1)} + p_{ABC(1,2)})\sin\phi + c\cos\phi \text{ along the } \beta \text{- characteristic line } ABC(1,1)ABC(1,2)
\]

\section{5. Discussion and Conclusions}

The solution for stress fields depend on the angle determined by the wedge semi-angle, \(\theta_1\). When the wedge is penetrated into the granular material surface, the particles move downwards. Since the values of \(\psi\) and \(p\) along the punch surface are constant, then the triangular region under the punch surface ABC, as in Figure 3, is formed where the stresses are all constants. The computed values of \(\psi\) and \(p\) in region ABC are given as follows

\[
\psi = 0.7854, \quad p = 13.016
\]

These results obtained were compared to the analytical solutions given in [4] and it obeys the solution. The granular material is assumed to be in dense, solid like state. The solution only refers to the initial motion after the punch and the numerical method for stress field under the punch surface described in this paper is simple and reliable. This was then applied to one type of boundary value problem and can be constructed to other types of boundary value problems in plastic flow. This will be a part of our future work.
