Abstract We study the asymptotic behavior (for \( t \to \infty \)) of solutions of the Cauchy problem for a nonlinear parabolic equation with a double nonlinearity, describing the diffusion of heat with nonlinear heat absorption at the critical value of the parameter \( \beta \). For numerical computations as an initial approximation we used founded the long time asymptotic of the solution. Numerical experiments and visualization were carried for one and two dimensional case.

Keywords Heat Conduction Problem, Critical Value of Parameter, Absorption, Maximum Principle, Numerical Computation, Visualization

1. Introduction

As is well known for the numerical computation of a nonlinear problem, the choice of the initial approximation is essential, which preserves the properties of the final speed of propagation, spatial localization, bounded and blow-up solutions, which guarantees convergence with a given accuracy to the solution of the problem with minimum number of iterations.

It is very important to establish the values of numerical parameters at which the nature of the asymptotic behavior of the solution will change. Such values of numeric parameters are called critical or critical values of the Fujita type. He first established this for the semi-linear heat equation [1]. At the critical parameters we can observe new effects such as infinite energy, localization and others.

In the domain \( Q = \{(t,x) : t > 0, x \in \mathbb{R}^N\} \) the following Cauchy problem

\[
\frac{\partial u}{\partial t} = \nabla \left( u^{m-1} \nabla u \right) - \nabla \cdot \left( \beta u^p \nabla u \right) - u^q \quad (1)
\]

\( u(0,x) = u_0(x), \ x \in \mathbb{R}^N \) \quad (2)

t and \( x \) are, respectively, the temporal and spatial coordinates where \( m \geq 1, k \geq 1, p \geq 2 \) given numerical parameters, characterizing the nonlinear medium

\( v() = \text{grad}(\cdot) , \ \beta = k(p-2) + m + \frac{p}{N} \) (\( \beta \), -critical value, \( N \)-size of dimension). In case \( k=1 \), critical value of parameter \( \beta \) was found in [2].

Problem (1.1) - (1.2) is the basis for modeling various processes of nonlinear heat diffusion, magnetic hydrodynamics, gas and liquid filtration, oil and gas, in the theory of non-Newtonian fluids, etc.

Under some suitable assumptions, the existence, uniqueness and regularity of a weak solution to the Cauchy problem (1.1) - (1.2) and their variants have been extensively investigated by many authors (see [3–5] and the references therein).

If the initial value \( u(x,0) = u_0(x) \) is respectively smooth, there are many papers on the solvability of the Cauchy problem (1.1)-(1.2), we can refer to Wu-Zhao [6], Gmira [7], Yang-Zhao [8], Zhao [9-11], Zhao-Yuan [12], Dibenedetto-Friedman [13], LiHia [14], Dibenedetto-Herrero [15], Beniland-Crandal Pierre [16], Zhao-Xu [17], Fan [18] and links to them for details.

A lot of works studied properties of solutions of problem with critical value of parameter \( \beta \) and were established asymptotic behavior for \( t \to \infty \) (see [1], [2], [19]-[27]).

The long time asymptotic of solutions has been established for the critical value of parameter \( \beta \) for problem (1.1)-(1.2) in case \( k=1, m=1, \beta_* = p - 1 + p / N \) in [19], case \( p=2, \beta_* = m + 2 / N \) in [20].

In [21] authors were established the long time asymptotic of solutions for the critical value of parameter...
\[ \beta = 1 + \frac{2}{N} \] for problem (1.1) - (1.2) in case \( m=1, \ p=2 \).

They considered following semi-linear parabolic equation

\[ u_t - \Delta u + u^\gamma = 0, \ t > 0 \] (3)

\[ u(0, x) = u_0(x) \geq 0 \] (4)

\[ \Delta = \sum_{i=1}^{N} \partial^2 / \partial x_i^2, \ \beta = 1 + \frac{2}{N} \]

The solution of problem (3) - (4) is “infinity” energy. The initial data is

\[ u_0(x) = o\{\exp(-\gamma |x|^2)\}, \ x \to +\infty \]

\[ \gamma > 0 \]

They proved that for problem (3) - (4) the long time asymptotic of the solutions is the following approximate self-similar solution

\[ u(t, x) = [(T + t)\ln(T + t)]^N g_\ast \left( \frac{x}{(T + t)^{1/2}} \right) \] (5)

For \( g_\ast \) function upper and lower bounds were obtained

\[ A \exp\left( -\frac{|x|^2}{4} \right) \leq g_\ast(\xi) \leq H \exp\left( -\frac{|x|^2}{4} \right) \frac{|x|^2}{T + t} \]

where \( A, H \) – constants.

For \( \beta 
eq 1 + \frac{2}{N} \), the approximate self-similar differs from (5), which means that for critical values the asymptotic of the solutions will change for \( t \to \infty \).

In [22] was considered following nonlinear heat equation with absorption

\[ u_t = \Delta(u^{\sigma+1}) - u^\beta \] in area \( Q = R^N \times (0, \infty) \) (6)

\[ u(x, 0) = u_0(x) \] for \( x \in R^N \) (7)

Authors established the long time asymptotic of the solution for the critical exponent \( \beta = \beta_\ast = \sigma + 1 + 2/N \).

The following asymptotic

\[ u(x, t) = ((T + t)\ln(T + t))^{-k} F(\xi; a) \] (8)

\[ \xi = x(T + t)^{-N/(N\sigma + 2)}, F(\xi; a) = C_0 (a^2 - |\xi|^2)^{1/\sigma} \]

\[ C_0 = [k\sigma / 2N(\sigma + 1)]^{1/\sigma}, T > 1 \]

where the value of the numerical parameter \( a \) is determined from the law of energy conservation

\[ \int w_M(x, t) \, dx = \int F(\xi; a) \, d\xi = M \]

\[ M = C_1 a^{N/k} \]

where \( C_1 = \pi^{N/2} C_0 B(N/2, 1 + 1/\sigma) / \Gamma(N/2) \)

\( B \) and \( \Gamma \) is beta and gamma of Euler function.

They proved that solution (8) is the long time asymptotic of the solution to problem (6) - (7) by constructing lower and upper solutions. The following lower and upper solution with variable \( a \)

\[ ((T + t)\log(T + t))^{1/\gamma} F(\xi; a_\ast) \leq u(x, t) \leq ((T + t)\log(T + t))^{1/\gamma} F(\xi; a_\ast) \]

\[ 0 < a_\ast < a_\ast \]

In [23] authors gave bounds for the blow-up rate of solution the following nonlinear parabolic equation

\[ u_t - div(u^{m-1} |Du|^{l-1} Du) = f(x)u^p \] in \( Q_T = \Omega(0, T), 0 < T < \infty \)

where \( f(x) \) is a radial function and for simplicity it taken like this \( f(x) = |x|^\sigma \), \( -\infty < \alpha < \min(N, \lambda + 1) \)

Here are some of them

\[ u(x, t) \leq \gamma(T - t)^{1/\beta} \]

Where \( \gamma > 0 \)

\[ 0 < m + \lambda - 1 < p < m + \lambda - 1 + (\lambda + 1 - \alpha) / N \]

\[ H = \frac{(p - m + \lambda - 1)}{p - m + \lambda + 1} \]

\[ B = \frac{\lambda + 1 - \alpha}{p - m + \lambda - 2} \]

(H gives the correct space-time scaling near the blow-up time, \( B \) gives the blow-up rate).

In [24] established conditions of norm of solution with critical exponent \( q^* = \frac{K + N}{N + 1} \) for following Cauchy problem

\[ u_t - div(u^{m-1} |Du|^{l-1} Du) = -\varepsilon |Du|^q + \delta u^p \] in \( R^N \times (0, T) \)

\[ u(x, 0) = u_0(x) \geq 0 \]

Here are some of them

\[ if \ q < q^* then \|u(t)\| \leq \gamma t^{-\delta} \]

\[ if \ q = q^* then \|u(t)\| \leq \gamma [\ln(t)]^{1/\gamma - 1} \]
here \( A = \frac{q - q^*}{H} (N_\nu + 1) \), \( H = (\lambda_1 + 1) (v - 1) - q (m + \lambda - 2) \),
\[ K = N (m + \lambda - 2) + \lambda + 1, \]
\[ \delta = 0, \varepsilon = 1, m + \lambda - 2 > 0. \]

In [25] the long time asymptotic of the solution were established for the following problem with critical parameter \( p_c = 1 + 2m/N \)
\[ u_t = -\Delta^m u^{p-1} u \text{ in area } R^N \times R_+ \]
\[ u(x, 0) = u_0(x). \]

Following asymptotic
\[ u(x, t) = \pm C_d t^{-N/2m} (\ln t)^{-N/(2m + Q)} \left[ f \left( \frac{x}{t^{1/2m}} \right) + o(1) \right] \]
where \( f \) is the rescaled kernel of the fundamental solution of the linear parabolic operator.

Mu et al. [26] studied the secondary critical exponent for the following \( p \)-Laplacian equation with slow decay initial values:
\[ \begin{align*}
\phi_t &= \text{div} \left( \left| \nabla u \right|^{p-2} \nabla u \right) + u^q, (x, t) \in R^N \times (0, T) \\
\phi(x, 0) &= \phi_0(x), x \in R^N
\end{align*} \]  
\[ (9) \]
\[ (10) \]
where \( p > 2, q > 1 \), and showed that, for \( q > q_c^* = p - 1 + (p/N) \), there exists a secondary critical exponent \( \alpha^* = (p/(q + 1 - p)) \) such that the solution \( \phi(x, t) \) of (1.9)-(1.10) blows up in finite time for the initial data \( \phi_0(x) \) which behaves like \( \left| x \right|^{-\alpha^*} \) at \( x = \infty \), if \( a \in (0, a_c^*) \), and there exists a global solution for the initial data \( \phi_0(x) \), which behaves like \( \left| x \right|^{-\alpha^*} \) at \( x = \infty \), if \( a \in (a_c^*, N) \).

J.-S. Guo and Y. Y. Guo [27] obtained the secondary critical exponent for the following porous medium type equation in high dimensions:
\[ \phi_t = \Delta u^m + u^p, (x, t) \in R^N \times (0, T) \]
\[ \phi(x, 0) = \phi_0(x), x \in R^N \]
\[ (11) \]
\[ (12) \]
where \( p > 1, m > 1 \) or max \( \{0, 1 - (2/N)\} < m < 1 \), \( \phi_0(x) \) is nonnegative bounded and continuous, and proved that for \( p > p_m^* = m + (2/N) \), there exists a secondary critical exponent \( \alpha^* = 2/(p - m) \) such that the solution \( \phi(x, t) \) of (1.11)-(1.12) blows up in finite time for the initial data \( \phi_0(x) \).

The authors of [28] considered the fast diffusion equation for large \( t \), when the degree of absorption is critical for the following equation
\[ \partial_t \phi - \Delta u^m + u^q = 0 \text{ in area } (0, \infty) \times R^N \]
\[ \phi(0, x) = \phi_0(x), x \in R^N \]
\[ q = q_c := m + \frac{2}{N} \]

They established a clear lower bound, which eliminates convergence to zero.

In this paper, we study the asymptotic behavior (for \( t \to \infty \)) of solutions of the Cauchy problem (1.1)-(2) for a nonlinear parabolic equation with a double nonlinearity, describing the diffusion of heat with nonlinear heat absorption at the critical value of the parameter \( p \).

2. Asymptotic of the Solution

Based on the method of standard equation [2], the solution to the problem (1)-(2) will be find in the following form
\[ \begin{align*}
\phi(t, x) &= \nu(t) (\phi(t, x), x) \phi(t) = (t \ln t)^{\frac{1}{\alpha c - 1}}
\end{align*} \]  
\[ (13) \]
Put (13) in (1) and select \( \tau(t) \)
\[ \tau(t) = \int (t \ln t)^{\frac{m + k(p - 2) - 1}{\beta - 1}} dt \]
For \( \nu(t, x) \) we get following equation
\[ \frac{\partial \nu}{\partial \tau} = \nabla \phi^m \phi \nabla \phi - \phi^q \phi^\theta - \phi^\theta \phi^\phi \]
\[ (14) \]
We note that for large \( t \) by the Hardy theorem on the behavior of the integral [2], the function \( \tau(t) \) has the following asymptotic
\[ \tau(t) \sim t^{\alpha_1} \ln^{\alpha_2} t, \quad t \to \infty \]
Where
\[ \alpha_1 = \frac{k(p - 2) + m - 1}{(p + (k(p - 2) + m)N)p}, \]
\[ \alpha_2 = \frac{k(p - 2) + m - 1}{(p + (k(p - 2) + m)N)p} + 1 \]
Now put \( \phi(t, x) = f(\xi), \quad \xi = x[\tau(t)]^{-1/p} \), in (14) we get an approximately self-similar equation:
To Asymptotic of the Solution of the Heat Conduction Problem with Double Nonlinearity with Absorption at a Critical Parameter

\[
\zeta^{1-N} \frac{d}{d\zeta} \left( \zeta^{N-1} f^{(N-1)} \right) - f \tau \frac{\beta}{\beta-1} \frac{\beta}{\beta-1} \frac{d}{d\zeta} \left( \zeta^{N-1} f^{(N-1)} \right) + \zeta \frac{d}{d\zeta} f - p f^{\beta-1} = 0
\]

(15)

We take as a generalized solution of the equation (15) the following function

\[
\bar{f}(\zeta) = \left( a - b \zeta^{\frac{p}{\beta-1}} \right) \left( k^{\beta-1} \right)
\]

(16)

\[b = (m+k(p-2)-1)/(k^{\beta-1} p^{\frac{p}{\beta-1}}), \quad m+k(p-2)-1 > 0\]

After putting (16) into (15) a self-similar equation transforms to

\[
L(f) = -N f^{\frac{1-p}{p}} - f^{\beta-1} \left( \frac{\beta}{\beta-1} \right) \left( \zeta^{N-1} f^{(N-1)} \right) + \frac{1}{\beta-1} (\ln t + 1)
\]

(17)

Theorem 1

Let \((z-1)(\beta, -1) - (p + zN) p < 0\) and

\[(\beta, -1)((p + z(N - 1)) p - z + 1) - p(p + zN) \]

Where

\[z = k(p - 2) + m, \quad \beta, \text{ mentioned number}\]

Then for \(t \to +\infty\) solution of problem (1) - (2) bounded above by function \(u_+(t, x)\)

\[\bar{u}(t, x) = \bar{u}(t) \bar{f}(\zeta(1 + \ln^{-1} t)), \quad \bar{f}(\zeta(1 + \ln^{-1} t)) = \left( a - b \zeta^{\frac{p}{\beta-1}} \right) \left( 1 + \frac{1}{\ln t} \right) \]

Proof

Show that \(u_+(t, x)\) is the lower solution of problem (1) - (2). After putting \(U_+(t, x)\) in (17), we get the following estimates

\[
\bar{f}(\zeta(1 + \ln^{-1} t)) \left( \frac{\beta}{\beta-1} \right) \left( \zeta^{N-1} f^{(N-1)} \right) + \frac{N}{p \tau u^{\beta-1}} \geq 0
\]

To satisfy these estimates, the following conditions are sufficient

\[
\frac{1}{\beta-1} + \frac{\ln t}{\beta-1} + \frac{N}{p \tau u^{\beta-1}} \geq 0
\]

These conditions are true due to conditions of the theorem 1.

Theorem 2.

Let

\[u \leq \left[ \frac{1}{\beta-1} \right] \left( \zeta^{N-1} f^{(N-1)} \right) \left( \zeta^{N-1} f^{(N-1)} \right) \]

(16)

\[z = k(p - 2) + m, \quad \beta, \text{ defined above}\]

Then for \(t \to +\infty\) solution of problem (1) - (2) bounded below by function \(u_-(t, x)\)

\[u(t, x) = u(t, x) = \bar{u}(t) \bar{f}(\zeta(1 + \ln^{-1} t)), \quad \bar{f}(\zeta(1 + \ln^{-1} t)) = \left( a - b \zeta^{\frac{p}{\beta-1}} \right) \left( 1 + \frac{1}{\ln t} \right) \]

Proof

Show that \(u_-(t, x)\) is the upper solution of problem (1) - (2). After putting \(U_-(t, x)\) in (17), we get the following estimates

\[
\bar{f}(\zeta(1 + \ln^{-1} t)) \left( \frac{\beta}{\beta-1} \right) \left( \zeta^{N-1} f^{(N-1)} \right) - \frac{N}{p \tau u^{\beta-1}} \geq 0
\]

These conditions are true due to conditions of the theorem 2.

From the last two theorems it follows that for all large \(t\) the self-similar solution \(\bar{u}(t) \bar{f}(\zeta)\) is bounded above and below

\[u(t, x) = \bar{u}(t) \bar{f}(\zeta) \geq u(t, x) \geq u_-(t, x) = \bar{u}(t) \bar{f}(\zeta(1 + \ln^{-1} t))\]

For \(t \to +\infty\) we get the following estimates

\[u(t, x) = \bar{u}(t) \bar{f}(\zeta) \geq u(t, x) \geq u_-(t, x) = \bar{u}(t) \bar{f}(\zeta)\]

3. Results of the Numerical Experiments

Problem (1) - (2) has no analytical solution. Therefore, we will discuss the result of the numerical experiments. To find a solution of problem at some point we are using numerical methods (see [29]-[31]). The resulting asymptotic of the solutions were used as an initial approximation for numerical computation.

3.1. One Dimensional Case (N=1)

From problem (1) - (2) we have following one dimensional nonlinear heat equation with initial and boundary conditions
For problem (18) we construct the spatial grid \( x \) with steps \( h \) and temporary grid with replace problem (18) implicit two-layer difference scheme and obtain the difference task with error equation (19)

\[
\begin{align*}
\frac{y_{i+1} - y_i}{\tau} &= \frac{1}{h} \left[ a_{i+1}(y^{(i+1)}) (y_{i+1} - y_i) - a_i(y^{(i)}) (y_i - y_{i-1}) \right] \\
&= \left( \frac{y_{i+1} - y_i}{h} \right)^\beta, \quad i = 1, 2, \ldots, n-1; \quad j = 0, 1, \ldots, m-1
\end{align*}
\]

(19) 

Where \( a_{i+1} \) and \( a_i \) are nonlinear terms of the problem (18). In our case \( a_{i+1} \) and \( a_i \) are thermal conductivity coefficients. To calculate \( a_{i+1} \) and \( a_i \) use the following formulas [29]

\[
\begin{align*}
a_{i+1}(y^{(i+1)}) &= \frac{1}{2} \left[ (y_{i+2}^{(i+1)})^\beta - (y_i^{(i+1)})^\beta \right] + \\
&= \frac{1}{2} \left[ (y_{i+2}^{(i+1)})^\beta - (y_i^{(i+1)})^\beta \right]
\end{align*}
\]

(20) 

\[
\begin{align*}
a_i(y^{(i)}) &= \frac{1}{2} \left[ (y_{i+1}^{(i)})^\beta - (y_{i-1}^{(i)})^\beta \right] + \\
&= \frac{1}{2} \left[ (y_{i+1}^{(i)})^\beta - (y_{i-1}^{(i)})^\beta \right]
\end{align*}
\]

(21) 

when \( i=1 \) \( a_i \) goes beyond the points, so following Milne formulas can be used[31]

\[
\begin{align*}
du &\sim -\frac{y_2 + 4y_1 - 3y_0}{2h} \\
&= \frac{3y_2 - 4y_1 + y_0}{2h}
\end{align*}
\]

Scheme (19) is absolutely stable and has the first order of approximation for \( \tau \), and the second for \( h \) [29].

System of algebraic equation (19) is nonlinear is relative to \( y^{i+1} \).

For solve a system of nonlinear equations (19), we apply an iterative method and obtain following system of algebraic equation [29]

\[
\begin{align*}
y_{i+1}^{s+1} - y_i^{s+1} &= \frac{1}{h} \left[ a_{i+1}(y_{i+1}^{s+1}) (y_{i+1}^{s+1} - y_i^{s+1}) - a_i(y_i^{s+1}) (y_i^{s+1} - y_{i-1}^{s+1}) \right] \\
&= a_i(y_i^{s+1}) (y_i^{s+1} - y_{i-1}^{s+1}) - (y_i^{s+1})^\beta
\end{align*}
\]

(22) 

where \( s = 0,1,2,\ldots \) initial and boundary conditions unchanged.

Now system of algebraic equation (3.1.5) is linear is relative to \( y_i^{s+1} \). As the initial iteration for \( y_i^{s+1} \) is taken from the previous time step \( y_i^0 \). When counting by an iterative scheme, the accuracy \( \varepsilon \) of the iteration is set and the process continues until execution the following conditions

\[
\max_{0 \leq i \leq n} |y_i^{s+1} - y_i^s| < \varepsilon
\]

Remark. In all numerical calculations we take \( \varepsilon = 10^{-3} \).

Let following notation

\[
y_0 = y, \quad y_i^{s+1} = \bar{y}_i.
\]

From different scheme (22) we will find tridiagonal matrix coefficients \( A, B, C, F \) and solve following system linear equations by method Thomas [29]

\[
\begin{align*}
\bar{y}_{i+1}^{s+1} - \bar{y}_{i}^{s+1} + B_{i+1}^{s+1} - B_i^{s+1} = \bar{F}_i, \quad i = 1, 2, \ldots, n - 1.
\end{align*}
\]

(22) 

\[
\begin{align*}
y_0 &= \chi_1 y_1 + \mu_1 \\
y_N &= \chi_2 y_N + \mu_2
\end{align*}
\]

(22) 

Where

\[
\begin{align*}
A_i &= \frac{\tau a_i (a_i^{s+1})^\beta}{h^2}, \\
B_i &= \frac{\tau a_{i+1} (a_i^{s+1})^\beta}{h^2}, \\
C_i &= A_i + B_i + 1, \\
F_i &= y_i^{s+1} - (y_i^{s+1})^\beta
\end{align*}
\]

3.2. Two-Dimensional Case (N=2)

From problem (1) - (2) we have following two-dimensional nonlinear heat equation with initial and boundary conditions

\[
\begin{align*}
\frac{\partial u}{\partial t} &= \frac{\partial}{\partial x} \left( u^{n-1} \frac{\partial u^{p-2}}{\partial x} \right) - u^6 \\
u(0,x) &= \psi(x) \geq 0, \quad 0 \leq x \leq b
\end{align*}
\]
To Asymptotic of the Solution of the Heat Conduction Problem
with Double Nonlinearity with Absorption at a Critical Parameter

\[
\frac{\partial u}{\partial t} = \left( \frac{\partial}{\partial x_1} \left( u^{m-1} \frac{\partial u^k}{\partial x_1} \right) \right) - u^\beta \quad (23)
\]

where

\[
u_1 = \mu(x,t), \quad u(0,x) = u_0(x) \geq 0, \quad 0 \leq x_\alpha \leq b_\alpha, \quad \alpha = 1,2.
\]

We construct the spatial grid \( x_{\alpha} (\alpha = 1,2) \) with steps \( h_i = \frac{b_i}{n_i} \) and \( h_2 = \frac{b_2}{n_2} \):

\[
\overline{x}_l = \{ x_i = (x_i, x_{i+1}) \}, \quad x_i = i h_i, \quad x_{i+1} = (i+1) h_i, \quad i, j = 0,1,\ldots,n_\alpha, \quad \alpha = 1,2.
\]

And time grid with \( \tau \):

\[
\overline{\tau}_l = \{ \tau_k = \tau r, \quad \tau > 0, \quad l = 0,1,\ldots,m, \quad \tau = T \}, \quad T > 0.
\]

For numerical solution of the Problem (23) used method of variable direction [30]

\[
\begin{align*}
y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^t &= \Lambda_1 y_{i,j}^{t+\frac{1}{2}} + \Lambda_2 y^t + q(y^t) \\
y_{i,j}^{t+1} - y_{i,j}^{t+\frac{1}{2}} &= \Lambda_1 y_{i,j}^{t+\frac{1}{2}} + \Lambda_2 y^{t+1} + q(y^{t+1})
\end{align*}
\]

where

\[
\begin{align*}
\Lambda_1 y^{t+\frac{1}{2}} &= \frac{1}{h_1} \left[ a_{i,j} (y^{t+\frac{1}{2}}) \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^{t} \right) - a_{i,j} (y^{t+\frac{1}{2}}) \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^{t} \right) \right] \\
\Lambda_2 y^t &= \frac{1}{h_2} \left[ b_{i,j} (y^t) \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^t \right) - b_{i,j} (y^t) \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^t \right) \right] \\
\Lambda_2 y^{t+1} &= \frac{1}{h_2} \left[ b_{i,j} (y^{t+1}) \left( y_{i,j}^{t+1} - y_{i,j}^{t+\frac{1}{2}} \right) - b_{i,j} (y^{t+1}) \left( y_{i,j}^{t+1} - y_{i,j}^{t+\frac{1}{2}} \right) \right]
\end{align*}
\]

\[
i, j = 1,2,\ldots,n_\alpha, \alpha = 1,2.
\]

\[
g(y^t) = -u^\beta
\]

For nonlinear part \( a_{i,j} (y^t) \) and \( a_{i,j} (y^{t+1}) \) were used the following approximations

\[
\begin{align*}
a_{i,j} (y^{t+\frac{1}{2}}) &= \frac{1}{2} \left[ \left( y_{i,j}^{t+\frac{1}{2}} \right)^{m-1} \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^{t} \right) \right] + \left( y_{i,j}^{t+\frac{1}{2}} \right)^{m-1} \left( y_{i,j}^{t+\frac{1}{2}} - y_{i,j}^{t} \right) \right]^{p-2}}{h_1} + \\
\end{align*}
\]
\[
\begin{align*}
\begin{cases}
y_{0}^{i,j} = u_{0}(x), & x \in \Omega_{k} \\
y_{i,j}^{k+1} = \phi^{k+1}, & \text{when } j = 0 \text{ and } j = n_{2} \\
y_{i,j}^{k+1/2} = \phi^{k+1/2}, & \text{when } i = 0 \text{ and } i = n_{1}
\end{cases}
\end{align*}
\] (25)

where \( \overline{\phi} = \frac{1}{2}(\phi^{k+1} + \phi^{k}) - \frac{\tau}{4} A_{2}(\phi^{k+1} - \phi^{k}) \). [30].

Let following notation

\[
y^{'} = y, \quad y_{i,j}^{k+1/2} = \overline{y}, \quad y_{i,j}^{k+1} = \bar{y}.
\]

For solve a system of nonlinear equations (3.2.2), we apply an iterative method and obtain following system of algebraic equation

\[
\begin{align*}
\frac{y_{i,j}^{k+1}}{0.5 \tau} &= \frac{1}{h_{1}^{2}} \left[ a_{i,j}(\bar{y}) \left( y_{i,j}^{k+1} - y_{i,j}^{k} \right) - a_{i,j}(\overline{y}) \left( \overline{y} - y_{i,j}^{k} \right) \right] + F_{i,j} = 0 \\
\frac{y_{i,j}^{k+1}}{0.5 \tau} &= \frac{1}{h_{2}^{2}} \left[ b_{i,j}(\bar{y}) \left( y_{i,j}^{k+1} - \bar{y} \right) - b_{i,j}(\overline{y}) \left( \overline{y} - \bar{y} \right) \right] + F_{i,j} = 0 
\end{align*}
\]

(26)

(27)

Now system of algebraic equation (26) is linear to relative \( y_{i,j}^{k+1} \) (27) is linear is relative \( \overline{y}_{i,j}^{k+1} \). As the initial iteration in (26) for \( \overline{y}_{i,j}^{0} \) \( y \) is taken from the previous time step \( \overline{y}_{i,j}^{0} = y_{i,j}^{0} \). When counting by an iterative scheme, the accuracy \( \varepsilon \) of the iteration is set and the process continues until the following conditions

\[
\max_{0 \leq i \leq n_{1}, 0 \leq j \leq n_{2}} \left| \overline{y}_{i,j}^{k+1} - y_{i,j}^{k+1} \right| < \varepsilon
\]

As the initial iteration in (3.2.5) for \( \overline{y}_{i,j}^{0} \) \( y \) is taken from the previous time step \( \overline{y}_{i,j}^{0} = y_{i,j}^{0} \). When counting by an iterative scheme, the accuracy \( \varepsilon \) of the iteration is set and the process continues until the following conditions

\[
\max_{0 \leq i \leq n_{1}, 0 \leq j \leq n_{2}} \left| \bar{y}_{i,j}^{k+1} - \overline{y}_{i,j}^{k+1} \right| < \varepsilon
\]

Remark. In all numerical calculations we take \( \varepsilon = 10^{-3} \).

Difference equation (26) can be written as

\[
\begin{align*}
A_{i,j} \bar{y}_{i,j+1} + C_{i,j} \bar{y}_{i,j} - B_{i,j} y_{i,j-1} &= -F_{i,j} \quad \text{for } i = 0 \text{ and } n_{1} \\
\bar{y} &= \phi, \quad \text{when } j = 0 \text{ and } j = n_{2}
\end{align*}
\]

(28)

and (27) as

\[
\begin{align*}
A_{i,j} \bar{y}_{i,j+1} + C_{i,j} \bar{y}_{i,j} - B_{i,j} y_{i,j-1} &= -F_{i,j} \quad \text{for } j = 0 \text{ and } n_{2} \\
\bar{y} &= \phi, \quad \text{when } j = 0 \text{ and } j = n_{2}
\end{align*}
\]

(29)

After we have 3 diagonal matrix equations with following coefficients A, B, C, F and can solve following system linear equations by method Thomas.

\[
\begin{align*}
A_{i,j} &= \frac{\tau a_{i,j}(\bar{y})^{1/2}}{2h_{1}^{2}}, \quad B_{i,j} = \frac{\tau a_{i,j+1}(\bar{y})^{1/2}}{2h_{1}^{2}}, \\
C_{i,j} &= A_{i,j} + B_{i,j} + 1, \quad F_{i,j} = y_{i,j} - \frac{\tau}{2} (\overline{y}_{i,j})^{\beta} + \frac{\tau}{2} \Lambda_{i,j} \overline{y}_{i,j}^{1/2}
\end{align*}
\]

The system of equations (28) is solved by lines \( j = 1, 2, \ldots, n_{2} - 1 \) and \( \bar{y} \) determined at all point of grid \( \Omega_{h} \), then system of equations (29) is solved by columns \( i = 1, 2, \ldots, n_{1} - 1 \) and \( \overline{y} \) determined at all point of grid \( \Omega_{h} \). During the transition from layer l+1 to layer l+2, the counting procedure is repeated.

3.3. Visualization

Notice that very important to found appropriate initial approximation of solution depending on value of numerical parameters. Therefore, an initial and a boundary values are calculated using the founded above following asymptotic

\[
u_{0}(t,x) = (t \ln t)^{-\frac{1}{b_{r}}} \left( a - b \left( \frac{t \ln t}{p} \right)^{-\frac{1}{b_{r}}} \right)^{p-1} \left( m + k(p - 2) - 1 \right)
\]

(30)

b = (m + k(p - 2) - 1) / (k^{p-2}(p)^{p-1}), m = k(p - 2) - 1 > 0,

\( \xi = x(t) \), \( \tau(t) = t^{\alpha}, \quad t^{\alpha} \ln t^{\alpha} \)

\[
\begin{align*}
\alpha_{l} &= \frac{k(p - 2) + m - 1}{(p + k(p - 2) + m) N p}, \\
\alpha_{r} &= \frac{k(p - 2) + m - 1}{(p + k(p - 2) + m) N p}
\end{align*}
\]
212 To Asymptotic of the Solution of the Heat Conduction Problem with Double Nonlinearity with Absorption at a Critical Parameter

\[
\begin{align*}
&k=2 \quad m=2 \quad p=3 \\
p=4 \quad m=4 \quad k=2
\end{align*}
\]
m=4 p=3 k=2

k=4 p=3 m=2

k=2 m=2 p=3
To Asymptotic of the Solution of the Heat Conduction Problem with Double Nonlinearity with Absorption at a Critical Parameter

$k=2 \quad m=3 \quad p=3$

$t=1$

$t=10$

$t=20$

$t=30$

$t=50$

$t>100$

$k=2 \quad m=3 \quad p=3$

$t=10$

$t=30$
As we can see from the figures, for large times and a critical value of parameter $\beta$, the solutions of the problem infinitely close to each other, which leads to localization.

4. Conclusions

As we see the asymptotic of the solution to problem (1)-(2) for the critical parameter $\beta$ changes its asymptotic for $t \to +\infty$. Proofs of the proposal based on principle of comparison solutions. The resulting asymptotic of the solutions were used as an initial approximation for numerical computation. As we now the final propagation velocity is a natural effect inherent in nonlinear processes. In all numerical experiments we got this effect. As a numerical experiment showed, founded asymptotic is a good initial approximation. The numerical results are in good agreement with the physics of this process.

We are currently investigating the convergence of schemes (24), (19) and the asymptotic stability of a solution (30).

In authors study the homogeneous Dirichlet problem for the following doubly nonlinear equation posed in a bounded domain in $\mathbb{R}^N$ with homogeneous boundary conditions and with non-negative and integrable data for the degenerate case $m(p-1)>1$ and the quasilinear case $m(p-1)=1$

\[
\begin{align*}
&\begin{cases}
\Delta_p u(t,x) = \nabla \cdot (|\nabla w|^{p-2} \nabla w), & x \in \Omega, \\
 u(0,x) = u_d(x), & x \in \Omega, \\
 u(t,x) = 0, & t > 0 \text{ and } x \in \partial \Omega.
\end{cases}
\end{align*}
\]

$\Delta_p w := \text{div}(\nabla w |^{p-2} \nabla w)$ is p-Laplacian operator, $p>1$, $m>0$.

They established the following long time asymptotic of the solution and gives rates

\[ u(t,x) = (t + s)^{-\alpha} h(r), \quad r = |x| (t + s)^{-\beta}, \]

where $\alpha, \beta$ are positive parameters and $h$ a real valued function satisfying a certain ODE.

The founded long time asymptotic of the solution (3.3.1) can be used for this problem with the additional absorption part for the critical parameter $\beta$ in case $m=1, k=m$.

In addition, the equation (17) can be obtained by multiplying the equation (15) on $\xi^{N-1}$ and integrating over the interval $(0, \xi)$. Kind of such an equation may be get using work [33].

At $k(p-2) + m = 1$ there is a special case. In this case function $f(\xi)$ looks like following

\[ f(\xi) = \exp(- (k^{p-2} \rho^p)^{1/p} \xi^{p/2}) \]

All this suggest that parameter $\beta$ is very sensitive to parameters k, p, m. Besides at $k(p-2) + m = 1$ the asymptotic of the solution will also change, which as in the
critical case, can discover new effects, properties, estimates.

For the equation with variable density which is given below, the critical value of parameter $\beta$ is also found. With it helps search the asymptotic of the solution with critical parameter possible. For a critical value of parameter $\beta$ is a very important and generalized case of problem (1) - (2).

$$ x^{-1} \frac{\partial u}{\partial t} = \nabla \left( \frac{u^{\gamma}}{\gamma} \nabla u \right) - |x|^{-1} u^\beta, $$

$$ u(0,x) = u_0(x), x \in \mathbb{R}^N $$

$$ u(t,x) = w(t, \varphi(x)) $$

$$ \frac{\partial w}{\partial t} = \varphi^{\beta - s} \frac{\varphi}{\partial \varphi} \left( \varphi^{\beta - s} w^{p - \beta} - \frac{\varphi}{\partial \varphi} \right) - w^s $$

$$ \varphi^p = p \left| x \right|^{p-1} / (p - l), s = p \frac{N - l}{p - l}, N > l, l < p $$

$$ \beta_* = k(p - 2) + p / s = k(p - 2) + p - l $$

The search for new effects of a variable density problem for a critical value of parameter $\beta$ is a very important and interesting study. It expands the possibilities of applied application of this study and this equation a more generalized case of problem (1) - (2).
