Received November 3, 2019; Revised December 25, 2019; Accepted January 10, 2020

Abstract We found new classes of exact models to the Einstein-Maxwell system of equations which describe the internal structure of a compact star made of strange matter considering the equation of state proposed by Rocha, Bernardo, de Avellar and Horvath in 2019. It has been assumed that this matter is composed of equal number of up, down and strange quarks and a small amount of electrons required to reaching the charge neutrality. If this hypothesis is correct, the neutron stars would be strange stars. We have chosen a particular form of gravitational potential $Z(x)$ that depends on an adjustable parameter related to degree of anisotropy of the models and the new solutions can be written in terms of elementary and polynomial functions. The obtained models satisfy all physical features expected in a realistic star and the expressions for mass, density and stellar radius are comparable with the experimental results.

Keywords Charge Neutrality, Gravitational Potential, Strange Stars, Anisotropy, Adjustable Parameter

1. Introduction

The analysis and description of gravitational collapse in ultracompacts objects has high importance in astrophysics and has attracted and influenced many physicists due to formulation of the general theory of relativity [1, 2]. One of the most fundamental problems in theoretical physics is finding exact solutions of the Einstein field equations [3]. The exact solutions as physical model of compact stars was studied by Delgaty and Lake [4] who constructed several analytical solutions that describe static spherically symmetric perfect fluid and it satisfies all the necessary conditions to be physically acceptable and interesting topic as a case research.

In the construction of models of compact stars, the researches of Schwarzschild [5], Tolman [6] and Oppenheimer and Volkoff [7] are very important. Schwarzschild [5] found analytical solutions that allowed describing a star with uniform density, Tolman [6] developed a method to find solutions of static spheres of fluid and Oppenheimer and Volkoff [7] used Tolman's solutions to study the gravitational balance of neutron stars. It is important to mention Chandrasekhar's contributions [8] in the model production of white dwarfs in presence of relativistic effects and the works of Baade and Zwicky [9] who propose the concept of neutron stars and identify an astronomic dense objects known as supernovas.

The description of the gravitational collapse and evolution of the compact objects has been a topic of great importance in general relativity. Recent experimental results in binary pulsars suggest that some compact objects could be quark stars [10]. The existence of quark stars in hydrostatic equilibrium was first suggested by Itoh [11] in a seminal treatment. The study of strange stars with quark matter has been a topic of great interest in the last decades since this could represent the most energetically favorable state of baryon matter [12].

Stellar models consisting of spherically symmetric distribution of matter with presence of anisotropy in the pressure have been widely considered in the frame of general relativity [13-25]. The existence of anisotropy within a star can be explained by the presence of a solid core, phase transitions, a type III super fluid, a pion condensation [26] or another physical phenomenon by the presence of an electrical field [27]. Many researchers and scientists have used a vast and great variety of mathematical techniques to try and test in order to obtain solutions of the Einstein-Maxwell field equations for anisotropic relativistic stars since it has been demonstrated by Komathiraj and Maharaj [28], Thirukkanesh and Maharaj [29], Maharaj et al.[30], Thirukkanesh and Ragel [31,32], Feroze and Siddiqui [33,34], Sunzu et al.[35], Pant et al. [36] and Malaver [37-40]. These analyses indicate that the system of Einstein-Maxwell equations is very important in the description of ultracompacts objects.

In order to analytically integrate field equations, the
choice of the appropriate equation of state allows obtaining models of compact stars to be physically acceptable [41]. Komathiraj and Maharaj [12], Malaver [42], Bombaci [43], Thirukkanesh and Maharaj [29], Dey et al [44] and Usov [27] assume linear equation of state for quark stars. Feroze and Siddiqui [33] consider a quadratic equation of state for the matter distribution and specify particular forms for the gravitational potential and electric field intensity. Mafa Takisa and Maharaj [45] obtained new exact solutions to the Einstein-Maxwell system of equations with a polytropic equation of state. Thirukkanesh and Ragel [10] have obtained particular models of anisotropic fluids with polytropic equation of state, which are consistent with the reported experimental observations. Malaver [46] generated new exact solutions to the Einstein-Maxwell system considering Van der Waals modified equation of state with polytropic exponent. More recently, Rocha et al.[41] presented a new model with anisotropic pressure and an equation of state that describes the internal structure of a compact star made of strange matter in the color flavor locked (CFL) phase. This matter is assumed to be composed of equal numbers of up, down and strange quarks and a small number of electrons needed to maintain the charge neutrality. If this hypothesis is correct, neutron stars could be strange stars or hybrid stars with a thin crust of nuclei.

In this paper, we generated a new class of anisotropic matter with CFL matter equation of state proposed for Rocha et al.[41] in a static spherically symmetric space-time using a gravitational potential $Z(x)$ which depends on an adjustable parameter $\eta$. We obtained some new class of static spherically symmetrical models for an uncharged anisotropic matter distribution where the variation of the parameter modifies the radial pressure, energy density, stellar radius and the mass of the compact objects. This article is organized as follows: In Section 2, we present Einstein’s field equations. In Section 3, we make a particular choice of gravitational potential $Z(x)$ that allows solving the field equations and we have obtained new models for uncharged anisotropic matter. In Section 4, physical acceptability conditions are discussed. In section 5, a physical analysis of the new solutions is performed. Finally, in Section 6, we make a conclusion about obtained and discussed results.

2. The Einstein-Maxwell Field Equations

Consider a spherically symmetric four-dimensional space-time so that whose line element is given in Schwarzschild coordinates by

$$ds^2 = -e^{2\nu(r)} dt^2 + e^{2\lambda(r)} dr^2 + r^2 (d\theta^2 + \sin^2 \theta d\phi^2)$$

(1)

where $v(r)$ and $\lambda(r)$ are the two arbitrary functions. For uncharged anisotropic fluids, the Einstein-Maxwell system of field equations are obtained as follows:

$$\frac{1}{r^2} (1 - e^{-2\nu}) + \frac{2\lambda'}{r} e^{-2\lambda} = \rho$$

(2)

$$- \frac{1}{r^2} (1 - e^{-2\nu}) + \frac{2v'}{r} e^{-2\lambda} = p_r$$

(3)

$$e^{-2\lambda} \left( v'' + v' + \frac{v'}{r} - \frac{\lambda'}{r} \right) = p_t$$

(4)

where $\rho$ is the energy density, $p_r$ is the radial pressure and $p_t$ is the tangential pressure, $\Delta$ is the anisotropy and primes denote differentiation with respect to $r$. Using the transformations suggested by Durgapal and Bannerji [47] as $x = cr^2$, $Z(x) = e^{-2\lambda(r)}$ and $A^2 y^2(x) = e^{2\nu(r)}$ where $A$ and $c$ are arbitrary constants, then the Einstein-Maxwell system has the equivalent form as follows:

$$\frac{1-Z}{x} - 2Z = \frac{\rho}{c}$$

(5)

$$4Z \frac{\dot{y}}{y} - \frac{1-Z}{x} = \frac{p_r}{c}$$

(6)

$$4xZ \frac{\ddot{y}}{y} + (4Z + 2x\dot{Z}) \frac{\dot{y}}{y} + \dot{Z} = \frac{p_t}{c}$$

(7)

$$4xZ \frac{\ddot{y}}{y} + \dot{Z} \left( 1 + 2x \frac{\dot{y}}{y} \right) + \frac{1-Z}{x} = \frac{\Delta}{c}$$

(8)

where $\Delta = p_t - p_r$ is the measure of anisotropy and dots denote differentiation with respect to $x$.

With the transformations of Durgapal and Bannerji [47], the mass within a radius $r$ of the sphere takes the form

$$M(r) = \frac{1}{4c^{3/2}} \int_0^r \sqrt{x} \rho(x) dx$$

(9)

In this paper, the equation of state for radial pressure is presented in the form

$$p_r = \alpha \rho + \beta \rho^{3/2} - \gamma$$

(10)

proposed by Rocha et al.[41]. In eq. (10) $\alpha, \beta$ and $\gamma$ are arbitrary constants and $\rho$ is the energy density.

3. Classes of Models

In this treatment, we have chosen the form of the
gravitational potential as \( Z(x) = (1 - \eta ax)^2 \) where \( a \) is a real constant and \( \eta \) is an adjustable parameter. This potential is well behaved and regular at the origin in the interior of the sphere. We have considered the particular cases for \( \eta = 3/2, 3 \).

For the case \( \eta = 3/2 \), using \( Z(x) \) in eq. (5), we obtain

\[
\rho = 3ac\left(3 - \frac{15}{4}ax\right) \quad (11)
\]

Substituting (11) into eq. (10), the radial pressure can be written in the form

\[
p_{r} = 3ac\left(3 - \frac{15}{4}ax\right) + \beta \left[3ac\left(3 - \frac{15}{4}ax\right)\right]^{1/2} - \gamma \quad (12)
\]

Using (11) in (9), the expression of the mass function is

\[
M(x) = \frac{3a(4 - 3ax)}{8\sqrt{c}} x^{3/2} \quad (13)
\]

With (11) and (12), eq. (6) becomes

\[
\frac{\dot{y}}{y} = \frac{3ac\left(3 - \frac{15}{4}ax\right)^{1/2} + \beta \left[3ac\left(3 - \frac{15}{4}ax\right)\right]^{1/2} - \gamma + \frac{3a - \frac{9}{4}a^2x}{4\left(1 - \frac{3}{2}ax\right)^2}}{4\left(1 - \frac{3}{2}ax\right)^2} \quad (14)
\]

Integrating (14), we have

\[
y(x) = c_{1}(3ax - 2)^{A^{*}} e^{\frac{5\beta\sqrt{6ac(3ax-2)}\text{arctan}\left(\frac{1}{2}\sqrt{-30a^2cx+24ac}{ac}\right)}{12ac(3ax-2)\sqrt{ac}}} - 6\beta\frac{\sqrt{-5a^2cx+4ac}}{ac+B} \quad (15)
\]

where for convenience we have let

\[
A^{*} = -\frac{5}{4}a - \frac{1}{4} \quad \text{and} \quad B = -6\alpha\sqrt{ac} - 6\alpha\sqrt{ac} + 4\gamma\sqrt{ac}
\]

\( c_{1} \) is the constant of integration.

The anisotropy factor \( \Delta \) is given by

\[
\Delta = 4ac\left(1 - \frac{3}{2}ax\right)^{2}\frac{\dot{y}}{y} - 3ac\left(1 - \frac{3}{2}ax\right)\left(1 + 2x\frac{\dot{y}}{y}\right) + 3ac - \frac{9}{4}a^{2}cx \quad (16)
\]

The metric functions \( e^{2\lambda} \) and \( e^{2\nu} \) can be written as

\[
e^{2\lambda} = \frac{1}{\left(1 - \frac{3}{2}ax\right)^{2}} \quad (17)
\]

\[
e^{2\nu} = A^{*}c_{1}(3ax - 2)^{2A^{*}} e^{\frac{5\beta\sqrt{6ac(3ax-2)}\text{arctan}\left(\frac{1}{2}\sqrt{-30a^2cx+24ac}{ac}\right)}{6ac(3ax-2)\sqrt{ac}}} - 6\beta\frac{\sqrt{-5a^2cx+4ac}}{ac+B} \quad (18)
\]

With \( \eta = 3 \), the expression for the energy density is

\[
\rho = 9ac(2 - 5ax) \quad (19)
\]

Replacing (19) in (10), we have the radial pressure as

\[
p_{r} = 9ac(2 - 5ax) + \beta[9ac(3 - 5ax)]^{1/2} - \gamma \quad (20)
\]
and the mass function is

$$M(x) = \frac{3a(2-3ax)}{2\sqrt{c}} x^{3/2}$$

(21)

With (19) and (20), the eq. (6) can be written as

$$\frac{\dot{y}}{y} = \frac{9\alpha a(2-5ax)}{4(1-3ax)^2} + \frac{\beta[9\alpha c(2-5ax)]^{1/2}}{4c(1-3ax)^2} - \frac{\gamma}{4c(1-3ax)^2} + \frac{6a - 9a^2 x}{4(1-3ax)^2}$$

(22)

Integrating (22), we obtain

$$y(x) = c_2 (3ax - 1)^{4/6} e^{\frac{5\beta \sqrt{3ac(3ax-1)} \arctan \left( \frac{1}{2} \sqrt{\frac{-15a^2 cx + 6ac}{ac}} \right)}{12ac(3ax-1) \sqrt{ac}}} - \frac{3\beta \sqrt{\left[-5a^2 cx + 2ac / ac \right]}}{6ac(3ax-1) \sqrt{ac} + \gamma \sqrt{ac}}$$

(23)

Again, for convenience we have let $C = -3a\alpha c \sqrt{ac} - 3ac \sqrt{ac} + \gamma \sqrt{ac}$

and $C_2$ is the constant of integration.

The metric functions $e^{2\lambda}$, $e^{2\nu}$ and the anisotropy factor $\Delta$ can be written as

$$e^{2\lambda} = \frac{1}{(1-3ax)^2}$$

(24)

$$e^{2\nu} = A^2 c_2^2 (3ax - 1)^{2\Delta} e^{\frac{5\beta \sqrt{3ac(3ax-1)} \arctan \left( \frac{1}{2} \sqrt{\frac{-15a^2 cx + 6ac}{ac}} \right)}{6ac(3ax-1) \sqrt{ac}}} + \frac{3\beta \sqrt{\left[-5a^2 cx + 2ac / ac \right]}}{6ac(3ax-1) \sqrt{ac} + \gamma \sqrt{ac}}$$

(25)

$$\Delta = 4xc(1-3ax)^2 \frac{\dot{y}}{y} - 6ac(1-3ax)^2 \left(1 + 2x \frac{\dot{y}}{y}\right) + 6ac - 9a^2 cx$$

(26)

4. Physical Acceptability Conditions

For a solution of the field equations to be physically acceptable [10, 48, 49], they must satisfy the following conditions:

i) Regularity of the gravitational potentials in the stellar interior and at the origin.

ii) The radial pressure should be positive and a decreasing function of radial coordinate.

iii) The energy density should be well defined, positive and a decreasing function of the radial parameter.

iv) $p_r > 0$ and $\rho > 0$ in the origin.

v) Any physically acceptable solution must satisfy the causality condition where the radial speed of sound should be less than speed of light throughout the model, i.e. $0 \leq \frac{dp_r}{d\rho} \leq 1$.

vi) For the anisotropic case, the radial and the tangential pressure are equal to zero at the centre $r=0$, i.e. $\Delta(r=0)=0$.

vii) In the surface of the sphere, it should be matched with the Schwarzschild exterior solution, for which the metric is given by

$$ds^2 = \left(1 - \frac{2M}{r}\right) dt^2 + \left(1 - \frac{2M}{r}\right)^{-1} dr^2 + r^2 \left(d\theta^2 + \sin^2 \theta d\phi^2 \right)$$

(27)

through the boundary $r=R$ where $M$ is the total mass of the star.

5. Physical Analysis of the New Models

For the case $\eta=3/2$, we have

$$e^{2\lambda(0)} = 1$$

$$e^{2\nu(0)} = A^2 c_1^2 \left(-2 \right)^{2\Delta} e^{-\frac{10 \beta \sqrt{6} \arctan \left( \sqrt{\beta} \right) + 12 \beta a + B}{24 \sqrt{ac} \sqrt{ac}}}$$

in the origin $r=0$ and

$$e^{2\lambda(r)} \bigg|_{r=0} = e^{2\nu(r)} \bigg|_{r=0} = 0$$

This shows that the potential gravitational is regular in the origin. In the centre $r = 0$, $\rho(0) = 9a\alpha c$ and
\[ p_r(0) = 9ac + \beta \sqrt{3ac} - \gamma, \] both are positive if \( a, \alpha, \beta, \gamma > 0 \). In the surface of the star \( r=R \), we have \( p_r(r = R) = 0 \) and

\[ \frac{dp}{dr} = -\frac{45}{2} a^2 c^2 r < 0 \] \hspace{1cm} (28)

According to the equations (28) and (29) the energy density and radial pressure decrease from the centre to the surface of the star. From (13), we have

\[ M(r) = \frac{3acr^2(4-3acr^2)}{8} \] \hspace{1cm} (30)

and the total mass of the star is

\[ M(r = R) = \frac{(180ac\alpha^2 - 20\alpha\gamma - 10\beta^2 + 10\sqrt{4\alpha\beta^2\gamma + \beta^4})^{3/2}}{67500\alpha^2 a^3 c^3} \] \hspace{1cm} (31)

If \( \alpha=1/5, \beta=1/10 \) and \( \gamma=0 \), the eq. (31) takes the form \( M(r = R) = \frac{24}{125} \sqrt{\frac{5}{ac}} \).

Matching conditions for \( r=R \) can be written as

\[ 1 - \frac{2M}{R} = A^2 y^2 (cr^2) \] \hspace{1cm} (32)

\[ 1 - \frac{2M}{R}^{-1} = \frac{1}{\left(1 - \frac{3}{2} acR^2 \right)^2} \] \hspace{1cm} (33)

In order to maintain causality, the radial sound speed defined as \( v_{sr}^2 = \frac{dp_r}{dp} \) should be within the limit \( 0 \leq v_{sr}^2 \leq 1 \) in the interior of the star [4]. In this model, we have:

\[ v_{sr}^2 = \frac{dp_r}{dp} = \alpha + \frac{\beta}{2 \sqrt{3ac \left(3 - \frac{15}{4} ac\right)}} \] \hspace{1cm} (34)

and for the eq.(34) we can impose the condition

\[ \beta + 2\alpha \sqrt{3ac \left(3 - \frac{15}{4} ac\right)} \leq 1 \] \hspace{1cm} (35)

With \( \eta=3 \), we have \( e^{2\eta(0)} = 1 \), \( e^{2\eta(0)} = A^2 c^2 (-1)^{2A} e^{6ac\sqrt{ac}} \) in the origin and
\[
\left( e^{2A(r)} \right)_{r=0} = \left( e^{2\nu(r)} \right)_{r=0} = 0 . \text{ Again the gravitational potential is regular in } r = 0 .
\]

In the centre \( \rho(0) = 18ac \) and \( p_r(0) = 18ac + 3\beta \sqrt{ac} - \gamma \), both are positive if \( a, \alpha, \beta, \gamma > 0 \). In the boundary of the star \( r = R \), we have \( p_r(0) = 0 \) and \( R = \frac{\sqrt{360ac \alpha^2 - 20\alpha \gamma - 10\beta^2 + 10\beta \sqrt{4\alpha \beta^2 \gamma + \beta^4}}}{30ac} \). If \( \alpha = 1/5, \beta = 1/10 \) and \( \gamma = 0 \), then we obtain the stellar radius \( R = \frac{1}{5} \sqrt{\frac{10}{ac}} \). This is a new value found for the radius of the star.

As the radial pressure and the energy density decrease from the centre to the surface of the star we have that for all \( 0 < r < R \)
\[
\frac{dp}{dr} = -90a^2c^2r < 0 \tag{36}
\]
\[
\frac{dp_r}{dr} = -90\alpha a^2c^2r - \frac{15\beta a^2c^2r}{\sqrt{ac(3 - 5acr^2)}} < 0 \tag{37}
\]

From (21), we get
\[
M(r) = \frac{3acr^3(2 - 3acr^2)}{2} \tag{38}
\]
and the total mass of the star is
\[
M(r = R) = \frac{360ac \alpha^2 - 20\alpha \gamma - 10\beta^2 + 10\beta \sqrt{4\alpha \beta^2 \gamma + \beta^4}}{540000a^2c^3} \tag{39}
\]
If \( \alpha = 1/5, \beta = 1/10 \) and \( \gamma = 0 \), the eq. (39) takes the form
\[
M(r = R) = \frac{12}{125} \sqrt{\frac{10}{ac}}.
\]
Matching conditions for \( r = R \) can be written as
\[
\left( 1 - \frac{2M}{R} \right) = A^2 \gamma^2 (cr^2) \quad \text{and} \quad \left( 1 - \frac{2M}{R} \right)^{-1} = \frac{1}{(1 - 3acR^2)}
\]
For this case, the condition \( 0 \leq V_{sr}^2 \leq 1 \), also implies that
\[
0 \leq \frac{\beta + 2\alpha \sqrt{9ac(2 - 5acr^2)}}{2\sqrt{9ac(2 - 5acr^2)}} \leq 1
\]
The figures 1, 2, 3, 4 and 5 represent the graphs of \( p_r, \rho, M(x), \Delta \) and \( V_{sr}^2 \), respectively with \( \eta = 3/2, \alpha = 1/5, \beta = 1/10, \gamma = 0, a = 0.028 \) and a stellar radius of \( r = 5.3 \text{ km} \).
Figure 1. Radial pressure vs radial coordinate for $\eta=3/2$, $\alpha=1/5$, $\beta=1/10$, $\gamma=0$ where $a=0.028$ and $c=1$.

Figure 2. Energy density vs radial coordinate for $\eta=3/2$, $\alpha=1/5$, $\beta=1/10$, $\gamma=0$ where $a=0.028$ and $c=1$.

Figure 3. Mass function vs radial coordinate for $\eta=3/2$, $\alpha=1/5$, $\beta=1/10$, $\gamma=0$ where $a=0.028$ and $c=1$.

Figure 4. Measure of anisotropy vs radial coordinate for $\eta=3/2$, $\alpha=1/5$, $\beta=1/10$, $\gamma=0$ where $a=0.028$ and $c=1$. 
In figure 1, it is observed that the radial pressure is finite and decreasing from the center to the surface of the star. In figure 2, the energy density is continuous, also is finite and monotonically decreasing function. In figure 3, the mass function is strictly increasing, continuous and finite. In figure 4, the measure of anisotropy is increasing and continuous in the stellar interior and Δ vanishes at the center and this means that the radial and tangential pressures should be equal in \( r = 0 \). The figure 5 shows that the condition \( 0 \leq v^2_{sr} \leq 1 \) is maintained throughout the interior of the star and satisfy the causality, which is a physical requirement for the construction of a realistic star [4].

6. Conclusions

In this research, we have generated some new class of exact models with an equation of state that considers CFL strange matter phase and anisotropy in the pressure where the gravitational potential \( Z \) depends on an adjustable parameter \( \eta \). All the obtained models are physically reasonable and satisfy the physical characteristics of a realistic star as are the regularity of the gravitational potentials at the origin, cancellation of anisotropy in \( r = 0 \), radial pressure finite at the centre and decreasing of the energy density and the radial pressure from the centre to the surface of the star. These solutions match with the Schwarzschild exterior metric at the boundary for each value of adjustable parameter and the CFL phase is modelled, as it is electrically neutral according to Rocha et al. [41].

The values calculated for energy density, mass and stellar radius could correspond to compact objects with real existence. For \( \eta = 3 \), the radius and total mass of the star is given by

\[
R(r = R) = \frac{1}{5} \sqrt{\frac{10}{ac}}
\]

and \( M(r = R) = \frac{12}{125} \sqrt{\frac{10}{ac}} \) with \( \alpha = 1/5, \beta = 1/10 \) and \( \gamma = 0 \). When \( \eta = 3/2 \),

\[
R(r = R) = \frac{1}{5} \sqrt{\frac{10}{ac}}
\]

and \( M(r = R) = \frac{12}{125} \sqrt{\frac{10}{ac}} \). We can then generate models with anisotropy in the pressure made of CFL strange matter with defined values of mass and radius. The values of \( \alpha, \beta, \gamma \) have been chosen in order to maintain the causality condition and the regularity of metric potentials inside the radius of the star.

With the CFL equation of state, the MIT bag model can be recovered as a particular case of this work by taking \( \beta = 0 \) in eq. (10) and generates families of exact solutions for the Einstein-Maxwell field equations for modeling relativistic compact objects, strange stars and configurations with anisotropic matter distribution.
