

resourcefulness and land. The adverse effect from climate change in the form of reduction of agricultural production ends up decelerating the growth of countries in Africa, since a greater proportion of the national income of most African countries is from agriculture. In addition, the agricultural sector aid as the source of livelihood (that is, source of employment) for most people in Africa [3]. Climate change and its impacts are actuality in Ghana. Studies have reported that Ghana's climatic conditions have changed in the past four decades [4] [5]. Over these decades, Ghana documented temperature increase of 1°C [4]. In the same time period, runoff and rainfall declined by about 20% and 30% respectively [5]. In Ghana, the livelihood backing (agriculture and forestry) and other critical natural resources for rural areas and the country's economy are not free from the grips of climate change in the six ecologic/geographic regions [4]. Yet, most of the studies have centered on environmental aspects of climate change vulnerability and biophysical, while impacts and adaptation works have mostly addressed problems at the national front. Few findings have addressed the social aspects of climate change impacts, vulnerability and adaptation strategies at the local level (households, rural communities, and districts). It is important for more research to center mostly on the social aspects of climate change vulnerability with in-depth examination of the underlying socio-economic statuses that ascertain how the populace reacts to and cope with climate change impacts at the local level. Assessing local level impacts, vulnerability and adaptation is discerning for the development of policy measures that address specific local level needs and avoid one-size-fit-all evaluation that often result from national scale climate change assessment.

Ghana is among countries where climate change is being experienced through the rise in temperatures and unpredictable rainfall across all ecological zones [6]. As far as water resources management and use are concerned, three climate change affiliated issues are relevant: extreme events brought about by changes in sea-level rise and variability, temperature regimes and rainfall [7]. Climate change remains an issue for the whole country, but climate variability is a major challenge, especially for rural areas that depend on natural resources and environmental factors/practices [8]. For rural indigenes without piped water, irregularity and severe in weather patterns (droughts and floods) instantly influence water availability and access, placing additional stresses on their daily activities [7]. According to [8] there is no doubt that the climate in Ghana has changed significantly with impacts being felt in every part of the country. Ghana is among countries where climate change is projected to create water stress by 2025 [7]. In northern Ghana, for instance, high temperatures that were previously recorded in March (peak of the dry season) are now being recorded also in January [9]. The start of the rainy season is becoming increasingly unpredictable. Previously, the rainy season commences in April and ended around late September or early October. Lately, the

rainy season starts in June or July with extreme heavy rainfall in September or October, often resulting in floods that destroy life, crops, and properties or ending abruptly and ending in drought conditions [9]. Ghana is experiencing increasing temperatures and irregular rainfall patterns [5] [10]. As these and other modifications become more pronounced in the coming decades, they will likely present challenges to our society and habitat/ environment. There are diverse impacts that climate change is impacting on our environment and livelihood.

For more than a decade, disaster insecurity, water and sanitation insecurity, climate change and energy insecurity have been acknowledged as prominent public health issues [11] [12]. Rise in global temperatures have been accompanied by variations in weather and climate. The planet's oceans and glaciers have also experienced several huge changes. According to [13] Africa is very vulnerable to outcomes of climate change. Accompanying to climate change and variability are rainfall variability, more extreme weather phenomena's and floods are experienced, which severely manifests in Ghana [14].

For decades now climate conditions keep changing making it unpredictable. This has caused continuous decrease in agriculture production, affected water resources and brought upon human's diseases and socio economic instability. Climate change is having a great impact on the agriculture of the Pungu area, which is their main source/origin of income, assessing the adaptation strategies of the impact of climate change in the Pungu community will help the ministry of food and agriculture generate better adaptation strategies for their agriculture and manage well the old adaptations they are using. Therefore, this study seeks to assess climate change adaptation strategies in Pungu community and specifically assesses adaptation strategies to ensure climate change impact on water resources and evaluates strategies employed for sustainable farming/agriculture under climate change in Pungu community, since climate change is having a major impact on agriculture of the Pungu area, which is their main source of income.

2. Materials and Methods

2.1. Study Area and Location

The study was undertaken at Pungu which lies within the Guinea Savannah woodlands in the Kassena Nankana East Municipal Assembly in the Upper East Region of Ghana, located about 4.5 km north east of Navrongo, the municipal capital (Figure 1). In Ghana, the Kassena Nankana East Municipality shares edges to the east with Kassena West District and Bolgatanga Municipal, the west with the Builsa District, to the north with Kassena Nankana West District and Burkina Faso and with West Mamprusi District at the south which is located in the Northern Region.

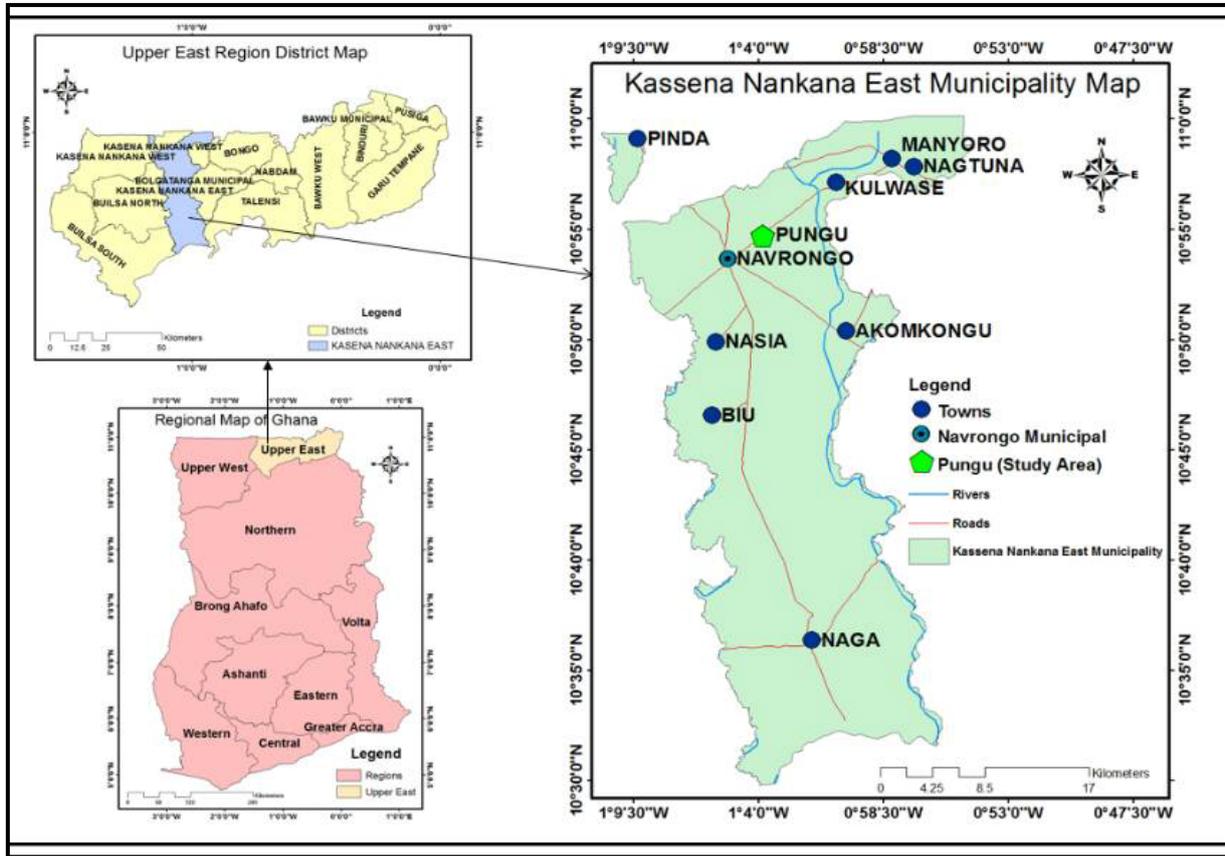

Figure 1. Map of Ghana showing the location of Pungu the study area

2.2. Soil and Vegetation

2.2.1. Vegetation

The administrative district is covered solely by the Sahel and Sudan-Savannah kinds of vegetation comprising open savannah with fire-swept grassland and deciduous trees. Several of the most densely vegetated parts of the Municipality can be found along river basins and forest reserves. However, exploitation of the original (virgin) vegetation cover by the activities of man has reduced it to open park land and the common trees found are Dawadawa, Baobab, Shea and Mangoes [15].

2.2.2. Soil

Savannah ochrosols and groundwater laterite are the predominant soils found in the municipality [16]. The northern and eastern parts of the Municipality are covered by the Savannah ochrosols, while the rest of the municipality is covered by groundwater laterite. The Savannah ochrosols are defined as porous, well drained, loamy, and mildly acidic and interspersed with patches of black or dark-grey clay soils [16]. The groundwater laterites are developed mainly over shale and granite and cover more than half of the municipality's land area. Because of the underlying rock type (granite), they become waterlogged during the rainfall period and dry out during the dry season, thus causing compacted/cemented layers of

iron-stone (hard pan), which makes cultivation difficult [15].

2.3. Climate

The climatic conditions experienced in the study area are the dry and wet seasons, which are influenced mainly by two (2) air masses – the North-East Trade winds and the South-westerlies (Tropical Maritime).

The harmattan air mass (North-East Trade Winds) is usually dry and dusty as it originates from the Sahara Desert. In the harmattan season rainfall is virtually absent and relative humidity rarely exceeds 20 per cent. The day time temperatures are high recording 42°Celsius (especially in February and March) and night time temperatures are as low as 18° Celsius [16]. The Municipality experiences the tropical maritime air mass between May and October with uni-modal rainfall averaging 950mm per annum with reference to [16]. This makes most of the youth in the Municipality idle during the dry seasons (November - April) since farming is the main occupation of the inhabitants and mainly rain fed [15].

2.4. Climate Change Impacts in Pungu

Climate changes have caused a lot of impacts nationwide and below are examples of these impacts on the people of

Pungu community. A change in rainfall pattern is one of the major climate change impact in Kassena Nankana East Municipality, Pungu community to be precise. Initially, the raining season starts from late April or early May to late July, but in recent times the rains start in late May or early June and ends in August. This makes the raining season shorter than it used to be. Changes in farming seasons and planting times are caused by changes in the raining season. Farmers wait on the start of the season to begin with their cultivation; therefore, planting seasons tend to change depending on the start of the rains. Farmers tend to cultivate crops that develop and yield in short period. Hunger/Famine is another impact caused by less food due to poor harvest due to small amount of rain or no rains. Farmers who put their produce on sale will have to keep to feed their families. Temperature increases and decreases drastically causing a lot of harm. Due to climate change, temperature may rise as high as 42°C and reduce to as low as 18°C in Pungu [16]. During high temperatures, soils and plants lose moisture through evaporation and transpiration respectively. Inhabitants of Pungu sleep outside their rooms due to heat produced by high temperatures and also to help prevent any heat related diseases such as Cerebrospinal Meningitis, heat stress, etc. Other diseases such as malaria may also result due to the extreme climatic changes in the area.

2.5. Methodology

Questionnaire administration was the tool used during the study process and simple random sampling techniques was adopted in the selection of units for probe/investigation. Simple random sampling necessitate that each member of the population stands an equal chance of being selected as a subject. The questionnaire was administered to know the various adaptation or coping strategies and to know how effective they are. The scope of the questionnaire includes assessing people’s knowledge on climate change, impacts of climate change and assessing the adaptation and coping strategies used to adjust to the impacts made by climate change. The questionnaires were administered to both male and female and across almost all walks of life in the area. The number of questionnaires administered was attained by calculating the sample size of the total population using the formula below by [17]:

$$n = \frac{N}{1+N(\gamma)^2}$$

where n is the sample size, N is the population and γ is the margin of error which in this study was chosen as 0.1 with confidence interval of 90%. The population of Pungu community is 7465 [16].

Hence,

$$n = \frac{7469}{1+(7469 \times 0.1 \times 0.1)} = 98.67 \sim 100$$

Thus 100 respondents were selected for the study meaning one hundred copies of questionnaires were administered as per the total population of Pungu and its surroundings, being 7469.

3. Results and Discussion

3.1. Gender

The total number of questionnaires administered was 100; with 55 males representing 55% of the total sample size and 45 females also representing 45% of the total sample population (Table 1).

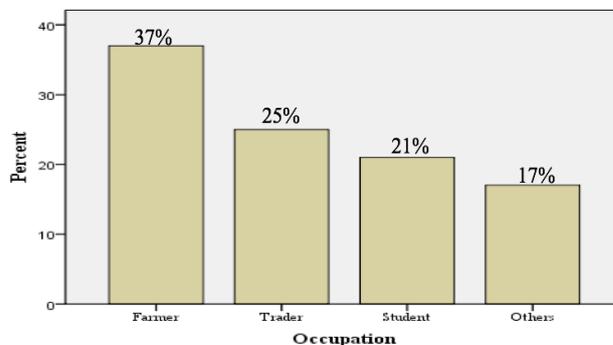

Table 1. Gender of respondents

Gender	Frequency	Percentage (%)
Male	55	55.0
Female	45	45.0
Total	100	100.0

Source: Authors’ Fieldwork (2014)

3.2. Occupation

Pungu is predominantly a farming community with a sizeable number of traders and other occupation. Out of the 100 respondents, 37 individuals representing 37% of the total sample population were farmers; 25 respondents (25%) were traders, 21 respondents (21%) were students (Figure 2). Literacy level scales down vulnerability by increasing people’s capabilities and admittance to information, attainment of skills and better risk acknowledgement thereby enhancing their strength to adapt with climate change adversities [18] and illiteracy serves as a barrier in facilitating understanding of the complex nature of hazards and appropriate responses to them [19], this implies that, 21% of the respondent stand a chance of coping with climate change adversities due to their level of literacy rate. About 17 respondents (17%) were into other occupations such as teaching, health, etc.

Source: Authors’ Fieldwork (2014)

Figure 2. Occupation of respondents

3.3. Adaptation Strategies

Adaptation strategies used in Pungu to cope with climate change are as follows;

3.3.1. Adaptation Strategies to Manage Water Resources

These are ways and means by which water resources are used in order to cope with impacts that climate change has on the water resources. Examples of such strategies are the use of shallow wells or hand-dug wells alongside boreholes as water resources and rainfall harvesting. These practices are used for agricultural purposes and domestic chores like cooking, washing, etc. There was no sign of a running stream in the town as at the time of the study (i.e. during the dry season).

Table 2 and Table 3 below show the distribution of respondents' views on these strategies;

Table 2. Response per shallow wells and hand-dug wells

	The use of shallow wells and hand-dug wells as an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	5	4	19	5	4	37
Trader	3	8	11	2	1	25
Student	1	7	10	3	0	21
Others	3	3	4	6	1	17
Total	12	22	44	16	6	100

Source: Authors' Fieldwork (2014)

From Table 2, 12 individuals representing 12% of the total sample population said the use of shallow wells and hand-dug wells is an excellent adaptation strategy. About 22 respondents (22%) also said is a very good strategy, 44 people (44%) also said it was Good. About 16 people (16%) however said it was fairly good and 6 individuals (6%) also said it was a poor adaption strategy. Table 3 shows that, 17 respondents representing 17% of the total sample population said it is an excellent adaptation strategy to harvest rain for use in the dry season. Another 17 respondents (17%) also said is a very good strategy, 26 people (26%) said it was Good. Some of the people (23%) however, said it was fairly good while 17 individuals (17%) also said it was a poor adaption strategy. This shows that, this particular strategy is not appreciated by the masses in the community.

Table 3. Response per harvesting of rain

	Harvesting rain for use in dry season as an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	6	5	15	6	5	37
Trader	3	10	4	0	8	25
Student	3	2	4	10	2	21
Others	5	0	3	7	2	17
Total	17	17	26	23	17	100

Source: Authors' Fieldwork (2014)

3.2. Adaptation Strategies for Food Security

These strategies are meant to ensure a constant and abundant food supply for the community and beyond. Examples of these strategies are; growing of vegetables and post-harvest storage. Table 4 and 5 indicate views of the respondents concerning these two examples;

Table 4. Response per growing of vegetables

	Growing vegetables as an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	8	19	2	5	3	37
Trader	5	3	11	6	0	25
Student	2	6	6	5	2	21
Others	4	4	6	1	2	17
Total	19	32	25	17	7	100

Source: Authors' Fieldwork (2014)

From Table 4, 19 individuals representing 19% of the total sample population said it is an excellent strategy to grow vegetables for food security. About 32 respondents (32%) also said it is a very good strategy, 25 people (25%) also said it was Good. About 17 people (17%) however said it was fairly good and 7 individuals (7%) also said it was a poor adaption strategy.

Since a greater percentage of the individuals from the total sample population responded positively to the growing of vegetables as an adaptation strategy, then it suggests that the strategy is acceptable to them.

Table 5. Response per post-harvest storage

	Post-harvest storage as an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	2	12	10	9	4	37
Trader	0	6	11	5	3	25
Student	0	5	9	5	2	21
Others	0	2	3	7	5	17
Total	2	25	33	26	14	100

Source: Authors' Fieldwork (2014)

From Table 5, 2 individuals representing 2% of the total sample population said it is a remarkable strategy to keep food after gathering as to ensure food security and safety. About 25 respondents (25%) also said it is a very good strategy, 33 people (33%) also said it was Good. Some of the people (26%) however said it was fairly good with 14 individuals (14%) also saying it was a poor adaption strategy. Even though a greater percentage of the individuals from the total sample population responded positively to post-harvest storage as an adaptation strategy, a sizable number of the population also thinks it is poor.

3.3. Adaptation Strategies for Health

These are strategies used to ensure disease prevention and control. Examples of these strategies are; sleeping outdoors to prevent heat related diseases such as Cerebrospinal Meningitis (CSM), heat stress among others and also sleeping under treated mosquito nets. Tables 6 and 7 show the views of the respondents concerning these two examples;

Table 6. Response per sleeping outdoors

	Sleeping outdoors to prevent heat related diseases is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	11	8	9	9	0	37
Trader	2	3	12	4	4	25
Student	10	6	2	3	0	21
Others	3	3	2	5	4	17
Total	26	20	25	21	8	100

Source: Authors' Fieldwork (2014)

From Table 6, 26 people representing 26% of the total sample population said it is an excellent strategy to sleep outside during heat seasons in order to prevent heat related diseases. About 20 respondents (20%) also said it is a very good strategy, 25 people (25%) also said it was Good. About 21 people (21%) however said it was fairly good and 8 individuals

(8%) also said it was a poor adaptation strategy.

Table 7. Response per the use of mosquito-treated nets

		Usage of mosquito nets is an adaptation strategy					Total
		Excellent	Very good	Good	Fairly good	Poor	
Occupation	Farmer	13	16	4	4	0	37
	Trader	8	8	5	2	2	25
	Student	5	11	4	0	1	21
	Others	5	5	2	3	2	17
Total		31	40	15	9	5	100

Source: Authors' Fieldwork (2014)

Table 7 shows that, 31 respondents representing 31% of the total sample population said it is a splendid strategy to sleep under treated-mosquito nets in order to prevent disease. About 40 respondents (40%) also said it is a very good strategy, 15 people (15%) also said it was Good. About 9 people (9%) however, said it was fairly good while 5 individuals (5%) also said it was a poor adaptation strategy. Since a greater percentage of the individuals from the total sample population responded positively to sleeping outside to prevent heat related diseases and also the use of mosquito-treated nets as adaptation strategy for health, then it suggests that these strategies are acceptable to the people of Pungu.

3.4. Adaptation Strategies for Agriculture

These are strategies used to ensure adequate utilization and efficient maintenance of the agricultural resources (lands, crops, etc.). Examples of this strategy are shifts in planting season to coincide with the start of rainy season, planting on raised ridges, farming during minor raining season, mixed farming, sales of livestock, improving soil nutrients, planting drought resistant crops varieties and the use of modern seeds.

Climate change introduces numerous uncertainties to the livelihoods of farming areas that rely heavily on the weather and climate [20] as reported by [21], the fundamental/basic elements of crop production such as soil, water and biodiversity are negatively affected by climate change.

Tables 8 to 15 show the views of respondents concerning the aforementioned strategies;

Table 8. Response per shifts in planting season

		Shifts in planting season to coincide with the start of the raining season is an adaptation strategy				Total
		Excellent	Very good	Good	Fairly good	
Occupation	Farmer	5	27	3	2	37
	Trader	9	11	5	0	25
	Student	8	9	3	1	21
	Others	5	8	4	0	17
Total		27	55	15	3	100

Source: Authors' Fieldwork (2014)

From Table 8, 27 people representing 27% of the total sample population said it is an excellent strategy to shift planting seasons to coincide with the time of rain in the year. About 55 respondents (55%) also said it is a very good strategy, 15 people (25%) also said it was Good and 3 people (3%) however said it was fairly good. None of the respondents voted for poor on this adaptation strategy.

Table 9. Response per planting on raised ridges

		Planting on raised ridges is an adaptation strategy					Total
		Excellent	Very good	Good	Fairly good	Poor	
Occupation	Farmer	4	11	13	9	0	37
	Trader	6	4	7	8	0	25
	Student	2	10	9	0	0	21
	Others	0	3	9	3	2	17
Total		12	28	38	20	2	100

Source: Authors' Fieldwork (2014)

Table 9 shows that, 12 people representing 12% of the total sample population said it is an excellent strategy to plant on raised ridges. About 28 respondents (28%) also said it is a very good strategy, 38 people (38%) also said it was Good and 20 people (20%) however said it was fairly good and 2 respondents (2%) voted for poor on this adaption strategy.

Low soil organic matter below 2% in the topsoil and high iron concretion levels with severe erosion susceptibility [22] is the nature of savannah zones soils hence, periodical incorporation of manure into the savannah zones soils is demanded [23] since limited availability of plant nutrients (in the form of phosphorus and nitrogen) is constraints to agricultural productivity in Pungu. These constraints are further impeded in the northern savanna zones by substantial topsoil losses through water and wind erosion [24], thus the need for planting on raised ridges in the Pungu community to support plant growth during the rainy season. However, during the dry season the farmers' should plant in the channels between the ridges to conserve irrigated water.

Table 10. Response per farming during minor raining season (late farming)

	Farming during minor raining season is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	5	2	3	21	6	37
Trader	1	7	4	7	6	25
Student	2	5	8	2	4	21
Others	0	4	4	4	5	17
Total	8	18	19	34	21	100

Source: Authors' Fieldwork (2014)

Northern Ghana, unlike the South does not necessarily have major and minor rainfall periods but rather a single raining season. In this study the minor season means from October to November when the rainfall season is coming to an end after peaking in August and September. Table 10 shows that, 8 people representing 8% of the total sample population said it is an excellent strategy to farm during minor raining season (late farming). About 18 respondents (18%) also said it is a very good strategy, 19 people (19%) also said it was Good and 34 people (34%) however said it was fairly good and 21 respondents (21%) voted for poor on this adaption strategy.

The Forest-Savanna Transition, Guinea Savanna and Coastal Savanna ecological zones are jugged out to be of the highest degree affected through shortened farming seasons and droughts [25]. This signifies that, the minor raining season is very inadequate for their farming activities and would therefore not be advisable to cultivate during this time.

Table 11. Response per mixed farming

	Mixed farming is an adaptation strategy				Total
	Excellent	Very good	Good	Fairly good	
Occupation Farmer	14	20	3	0	37
Trader	6	9	5	5	25
Student	8	9	4	0	21
Others	3	7	6	1	17
Total	31	45	18	6	100

Source: Authors' Fieldwork (2014)

According to Table 11 above, 31 respondents representing 31% of the total sample population said it is an excellent strategy to carry out mixed farming. About 45 respondents (45%) also said it is a very good strategy, 18 people (18%) also said it was Good. About 6 people (9%) however said it was fairly good while none of the respondents voted for poor on this adaption strategy.

This signifies that it is a highly acceptable strategy and needs to be encouraged among the residents of Pungu since most smallholder farmers in Pungu combine different approaches to meet food security and their cash flow needs.

Table 12. Response per sale of livestock

	Sales of livestock is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	3	19	7	6	2	37
Trader	2	5	4	7	7	25
Student	2	14	3	0	2	21
Others	2	2	4	1	8	17
Total	9	40	18	14	19	100

Source: Authors' Fieldwork (2014)

Table 12 shows that, 9 people representing 9% of the total sample population said it is an excellent strategy to sell livestock in order to get income to improve farming practices, livelihood and implements. 40 respondents (40%) also said it is a very good strategy, 18 people (18%) also said it was Good and 14 people (14%) however said it was fairly good and 19 respondents (19%) voted for poor on this adaption strategy.

This signifies that, the response is defused and therefore the strategy is not out rightly acceptable. However, 9% excellent and 40% very good indicates that livestock rearing should be encouraged as an adaptation strategy in the area since livestock production will help to generate income for livelihood support to the people of Pungu community.

Table 13. Response per soil nutrient improvement

	Improving soil nutrients is an adaptation strategy				Total
	Excellent	Very good	Good	Fairly good	
Occupation Farmer	10	22	5	0	37
Trader	6	5	10	4	25
Student	10	4	7	0	21
Others	5	7	5	0	17
Total	31	38	27	4	100

Source: Authors' Fieldwork (2014)

From Table 13, 31 people representing 31% of the total sample population said it is an excellent strategy to improve soil nutrients. About 38 respondents (38%) also said it is a very good strategy, 27 people (27%) also said it was Good and 4 people (4%) however said it was fairly good. None of the respondents voted for poor on this adaption strategy. According to this response, the use of manure (poultry droppings, cow dung, etc.) and fertilizers to improve the soil nutrients to augment fertility of the land is highly acceptable.

Table 14. Response per planting drought resistant crop varieties and fruits

	Planting drought resistant crop varieties and fruits					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	5	6	19	5	2	37
Trader	7	9	6	2	1	25
Student	1	10	3	5	2	21
Others	3	5	2	5	2	17
Total	16	30	30	17	7	100

Source: Authors' Fieldwork (2014)

Table 14 shows that, 16 people representing 16% of the total sample population said it is an excellent strategy to plant drought resistant crop varieties and fruits. About 30 respondents (30%) also said it is a very good strategy, 30 people (30%) also said it was Good and 17 people (17%) however said it was fairly good and 7 respondents (7%) voted for poor on this adaption strategy. The response indicates that introduction of drought resistant crops will be welcomed by the residents of the area.

Table 15. Response per the use of modern seeds

	Use of modern seeds is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	6	1	10	13	7	37
Trader	3	3	5	8	6	25
Student	3	4	5	7	2	21
Others	2	4	2	6	3	17
Total	14	12	22	34	18	100

Source: Authors' Fieldwork (2014)

Table 15 shows that, 14 people representing 14% of the total sample population said it is an excellent strategy to use modern seed. About 12 respondents (12%) also said it is a very good strategy, 22 people (22%) also said it was Good and 34 people (34%) however said it was fairly good and 18 respondents (18%) voted for poor on this adaption strategy.

This signifies that, the response is defused and therefore the strategy is not out rightly acceptable. This is due to the fact that most of the indigenes who indulge in subsistence farming do not get a supply of these types of seeds. Others who may acquire them also mostly do not apply the most required precautions concerning the use of these seeds.

3.3.5. Adaptation Strategies for Socio-Economic Stability

These are strategies employed during non-planting season in order to ensure sustained livelihood. Examples of this strategy are migration to other parts of the country and economic diversity (e.g. pito brewing). Table 16 shows the views of respondents concerning the aforementioned strategies;

Table 16. Response per migration to other parts of the country

	Migration to other parts of the country is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	2	2	0	14	19	37
Trader	1	5	3	6	10	25
Student	2	0	4	4	11	21
Others	1	0	1	1	14	17
Total	6	7	8	25	54	100

Source: Authors' Fieldwork (2014)

Owing to Table 16, 6 people representing 6% of the total sample population said it is an excellent strategy to migrate to other parts of the country to quest greener pastures in times of the non-farming seasons. About 7 respondents (7%) also said it is a very good strategy, 8 people (8%) also said it was Good and 25 people (25%) however said it was fairly good and 54 respondents (54%) voted for poor on this adaptation strategy. This demonstrates that, it is highly unacceptable to migrate to other parts of the country to seek greener pastures during non-planting season. They would rather stay in the community and wait for the rains to set in.

Table 17. Responses per economic diversification (basketry, pito brewing, etc.)

	Economic diversification (e.g. weaving of baskets) is an adaptation strategy					Total
	Excellent	Very good	Good	Fairly good	Poor	
Occupation Farmer	1	7	14	10	5	37
Trader	2	5	9	7	2	25
Student	0	2	4	12	3	21
Others	2	1	4	7	3	17
Total	5	15	31	36	13	100

Source: Authors' Fieldwork (2014)

Table 17 shows that 5 people representing 5% of the total sample population said it is an excellent strategy to embark on economic diversification. About 15 respondents (15%) also said it is a very good strategy, 31 people (31%) also said it was Good and 36 people (36%) however said it was fairly good and 13 respondents (13%) voted for poor on this adaptation strategy.

This also shows a defused response and therefore the strategy is not out rightly acceptable to the respondents.

The general findings of the study brought to light a better understanding about the adaptation strategies relationship of health, water resource managements, agriculture, food security and socio-economic stability on climate change effect in Pungu. Based on the review, we can infer that, farming as an occupation tend to have more economically active dependents on rainfall which in turn increases vulnerability in terms of occupation since farming is the predominate occupation in the area and rainfall is the primary source for indulging in farming activities in Pungu. In relation to occupation, since the Pungu is predominantly a farming area, a lot of the trader's trade in farm produce and as a result a high linkage is expected since these two (farming and trade) occupations largely depend on water and the environment if they are to see any gains. Additionally, the high link may be due to the fact that most of the traders are either related to the farmers or work directly with them. On the other hand, a smaller relation was observed between Farmers and Others (students and others) occupation. This was possibly due to the fact that these other occupations were not directly related to farming. Relating to health, change in temperature decides the sleeping adaptation strategy to be used by inhabitants since the breed of mosquito and heat related disease are predominant in the rainy season and high temperature periods respectively. People who are literate (students) depend more on information to attain skills that have influenced on climate-sensitive occupations like farming since they are able to diversify occupations or source of income to generate some manner of livelihood insurance against life uncertainties in order to reduce access to climate change vulnerabilities or impacts with high level of risk acknowledgement to their livelihoods. The use of shallow wells or hand-dug wells alongside boreholes as water resources and rainfall harvesting are the main domestic and agriculture water management adaptation strategies used in Pungu. Access to storage and the utilization of post harvest practices known by the Pungu people, post-harvest storage was the excellent adaptation strategy effectively utilized for food security. Diversified income sources such as trading, or migrating to southern part of the country to work provide some form of income and welfare insurance against shocks and reduces vulnerability to delay in planting in the farming season as a results of rainfall delay and off-farming seasons. In Pungu, occupations that depend primarily on the climate for production tend to be farming which was realized to be

vulnerable to climate change, hence changing climatic conditions disrupts production which in turn affect livelihood. Information on mixed farming dissemination by correspondence revealed the access to income generation from the sales of livestock and the use of the farm yard manure in enriching the soil as agriculture adaptation strategy. Economic diversification information of Pungu was known to promote resilience in the face of climate change events but limited access to relevant climate change information increases vulnerability to Pungu people because, heavy dependency on agriculture activities solely indicates narrow range of livelihood options but off-farm season activities provides security for socio-economic stability.

4. Conclusions

Adaptation strategies identified in Pungu were grouped into five categories, namely; health, water resource managements, agriculture, food security and socio-economic stability.

Two adaptation strategies were identified under health in Pungu and these strategies pertain to the extremities in temperatures. When temperatures are high, residents sleep outdoors to prevent heat related diseases such as Cerebrospinal meningitis and heat stress. Also during the raining season, residents sleep in treated mosquito nets due to the increase in the breed of mosquitoes.

The inhabitants of Pungu community are mostly farmers by occupation, and their main source of water for farming is the rains. Alterations in rainfall forms have caused them to shift their planting times to coincide with beginning of the rains. Some of the farmers have as well resorted to mixed farming and planting of drought resistant crop varieties. They also improve the fertility of the soil by the application of manure or fertilizers for high yield. The sale of livestock has also aided in the enhanced livelihood of the people of Pungu community.

Post-harvest culture which ensures efficient storage of food for posterity and cultivation of vegetables for use and sale in the markets is also practiced by the indigenes of Pungu.

During off-farming season or when farming activities are not providing enough to sustain the residents of Pungu, some resort to different occupations such as brewing of pito, rendering security services to local businesses among others. Others however migrate to other parts of the country to seek greener pastures.

It is recommended that more seminars and workshops should be held by municipal assembly on the awareness of climate change, its impacts and adaptation strategies in Pungu. The Ministry of Food and Agriculture (MoFA) should intensify their extension service and make provisions for all farmers; both commercial and subsistence and also innovate the farmers to more modern

adaptation strategies such as the use of improved seeds.
